

Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

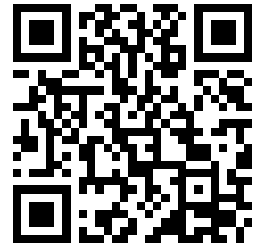
Wir bitten Sie um Einhaltung folgender Richtlinien:

+ *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.

+ *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.

+ *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.

+ *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. Gehen Sie nicht davon aus, dass das Erscheinen eines Buchs in Google Buchsuche bedeutet, dass es in jeder Form und überall auf der Welt verwendet werden kann. Eine Urheberrechtsverletzung kann schwerwiegende Folgen haben.



Über Google Buchsuche

Das Ziel von Google besteht darin, die weltweiten Informationen zu organisieren und allgemein nutzbar und zugänglich zu machen. Google Buchsuche hilft Lesern dabei, die Bücher dieser Welt zu entdecken, und unterstützt Autoren und Verleger dabei, neue Zielgruppen zu erreichen. Den gesamten Buchtext können Sie im Internet unter `http://books.google.com` durchsuchen.

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

LIST OF ILLUSTRATIONS.

Photoprints of Sections of the Spinal Cord accompanying paper on the Relationship of Some Forms of Combined Degenerations of the Spinal Cord to one another and to Anæmia (Dr. J. S. R. Russell), 6, 8, 10

Cardiac and Chronographic Tracings illustrating paper on the Heart-Radial Interval and a hitherto unknown Method of Compensation in Aortic Regurgitation (Dr. P. M. Chapman), 21, 22

Diagrams and Photoprint illustrating paper on a case of Complete Rupture of the Aorta presenting some extraordinary features (Dr. R. Petch), 85, 86

Diagrams illustrating clinical lecture on Fracture of the Neck of the Femur in Childhood (Mr. R. H. Russell), 126

Skiagram of Halfpennies impacted in the Œsophagus for five and six months respectively revealed by x rays and removed (Mr. A. W. M. Robson), 138

Full-length Photoprint of a case of Pemphigus Serpiginosus (Dr. R. Y. Aitken), 139

Ori-nasal Inhalation Tube (Mr. H. B. Beale), 154

Sketch showing details of Enterectomy and Cœlio-colostomy accompanying paper on Intestinal Cancer and its Treatment (Mr. J. Greig Smith), 190, 191, 192

Portrait of a case of Acromegaly and Photoprint of the Base of the Skull showing Enlarged Pituitary Body *in situ* (Mr. J. B. Neale and Dr. E. J. Smyth), 193, 194

Chemical Formulæ represented diagrammatically and Graphic Lines illustrating paper on Piperidine as a Uric Acid Solvent (Dr. F. W. Tunnicliffe and Mr. Otto Rosenheim), 198, 200, 201, 202, 203

Portrait of a Patient and Sketch representing Thrombosis of the Veins accompanying paper on cases of Extensive Venous Thrombosis associated with Severe Rheumatic Carditis (Dr. W. B. Cheadle and Dr. D. B. Lees), 208

Temperature Chart of an anomalous case of Continued Fever with Perforations of the Intestine (Dr. S. H. Snell), 253

Diagrams showing the Prevalence of Tuberculosis, Tetanus, Pneumonia, Broncho-pneumonia, and Pleuro-pneumonia, illustrating paper on the Effects of Drying of the Soil upon the Public Health of Buenos Ayres (Dr. J. T. R. Davison), 315, 316

Instrument for Stretching Urethral Strictures (Mr. R. Harrison), 319

Diagrams accompanying paper on Pregnancy simulating Pedunculated Fibroid (Dr. E. P. Thurstan), 322

Photoprint showing Cartilaginous Mass in the Adenoid Tissue of the Tonsil and Photomicrographs of Sections of a Nodule, described in paper on Cartilaginous and Bony Nodules in the Tonsil (Dr. H. Walsham), 394, 395

Separate Plate containing six Illustrations showing the Microbe of Pictou Cattle Disease, Sections of Liver of Cow, Rabbit, and Human Subject and Diplococci found in the Human Liver in Progressive Cirrhosis, accompanying paper on the Bacteriology of Progressive Cirrhosis of the Liver (Dr. J. G. Adami), 396

Diagram of Operation of Gastrostomy accompanying paper on Gastrostomy performed by the Kader-Senn Method (Mr. A. E. Maylard), 476

Apparatus for the Treatment of Fracture of the Patella (Mr. H. Bigg), 481

A new pattern of Uterine Replacer (Dr. F. J. Hicks), 488

Diagram showing the appearance of Coccidia in the Mosquito as described in paper on the Rôle of the Mosquito in the Evolution of the Malaria Parasite (Surgeon-Major R. Ross and Dr. P. Manson), 489

Section of Spinal Column showing Partial Destruction of Vertebræ accompanying paper on Modern Methods of Treatment of Caries of the Spine (Mr. Noble Smith), 549

Drawings of Five Instruments contained in Wire Suture-case (Mr. T. S. Carter), 558

Photoprint of an Embryological Curiosity (Dr. J. R. Macmahon), 687

A New Aspirator (Dr. W. Catto), 695

Five-shilling Stamp of the Prince of Wales's Hospital Fund, 709

Chart showing the Influence of Malaria in modifying the Temperature of Typhoid Fever (Dr. F. Arnold), 773

Three-way Cock for administering Nitrous Oxide Gas and Ether, for Use with Clover's Inhalers (Dr. J. A. Codd), 811

Improved Aseptic Hypodermic Syringe and Case (Dr. E. M. Jenkins), 811

New Catheter Dish (Mr. H. de P. B. Veale), 811

Modified Uterine Sound (Mr. A. Duke), 812

New Anæsthetic Bottle, 812

Diagrams of the Limbs and their Joints in the Horse and the Human Subject illustrating paper on the Influence of Position in Fractures and Dislocations (Dr. E. M. Corner), 859, 860, 861

Diagrams of the Thorax and Abdomen accompanying paper on a case of Cancer of the Pylorus (Dr. J. M. Clarke), 866, 867

Surgical Dressing Table (Dr. H. W. G. Macleod), 939

Plans of the Thompson-Yates Laboratories of Physiology and Pathology, University College, Liverpool, 954

Drawings of Hand and Arm showing a case of Hysterical Contraction of the Forearm successfully treated by Suggestion (Dr. S. K. Mullick), 984

Skiagram of Normal Chest and Skiagram of Chest of Chronic Pulmonary Tuberculosis showing Cavities at both Apices, described in paper on the X Rays in Diseases of the Chest (Dr. H. Walsham), 989

New Urethral Syringe (Mr. R. Stoney), 998

New Dressing Tray (Mr. S. Grubb), 998

Cutting Forceps for Use in the Treatment of Laryngeal Phthisis (Mr. K. Lake), 1068

Full-length Photoprints of a Child accompanying Description of a case of Chronic Infantile Meningitis with Basal Drainage (Dr. W. Overend and Mr. W. F. Cross), 1107

Drawing of Skull and Photoprints and Microphotographs of a Tumour accompanying Description of Uncommon Cases of Operation on the Brain (Mr. J. H. Nicoll), 1114, 1116, 1117

Graphic Curves illustrating the occurrence of Rheumatism in Children subsequent to an Attack of Chorea (Dr. F. E. Batten), 1195

Photoprints of Feet and Legs accompanying paper on a New Method of Restoring the Absent Function of Muscles in Infantile Paralysis (Mr. Noble Smith), 1196, 1197

Radiogram showing Deformity of Head of Tibia resulting from Fracture (Dr. L. Molloy), 1198

Full-length Photoprint of Patient presenting Extreme Deformity of the Lower Extremities (Mr. W. H. Battle), 1200

Metal A.C.E. Inhaler with a Simple Means of varying the Air-supply (Dr. W. J. McCardie), 1208

Amputation Retractor (Dr. F. W. Collinson), 1209

International Monument to Hans Wilhelm Meyer erected in Copenhagen, 1221

Graphic Curves illustrating Changes in Excretion of Urea and Nitrogen described in paper on Myxœdema and Allied Disorders (Dr. W. M. Ord), 1248

Lithotrite, Aspirating Catheter and Stylet described in paper on the Surgery of Stone in the Bladder (Mr. R. Harrison), 1254

Photoprint of Ileo-cæcal Junction and Appendix illustrating article on Acute Ileo-cæcal Intussusception (Mr. J. H. Ray), 1263

Saw for Removing Plaster-of-Paris and Other Casings, 1274

Graphic Curves showing Hourly Excretion of Urea by a Woman whose Stomach had been completely Removed (Dr. Carl Schlatter), 1317, 1318

Combined Tongue Depressor and Thermometer Case (Mr. J. B. Gabe), 1341

Hydrocele Injection Apparatus (Dr. Cuthbert Bowen), 1341

Aseptic Female Catheter Stand, 1341

Portrait of the late Surgeon-General W. C. Maclean, C.B., 1361

Eight Drawings of Apparatus employed in the Treatment of Neuralgia and Rheumatism by Currents of Hot Air (Dr. W. Taylor), 1385, 1386, 1387, 1388

Portrait of Patient illustrating paper on the Cure of Left Carotid Aneurysm by manipulation (Mr. R. Slocock), 1389

Statistical Diagrams illustrating the Result of the Treatment of Diphtheria by Antitoxin in London compared with that in Paris and Berlin (Dr. L. Cobbett), 1459

Drawings illustrating paper on the Mosquito and the Malaria "Parasite" (Lieut.-Col. E. Lawrie), 1468

Improved Form of Axis-traction Midwifery Forceps (Dr. G. P. Mathew), 1484

Digitized by Google

LIST OF ILLUSTRATIONS—(*Continued*).

New Pattern of Tourniquet, 1484

Improved Ormsby Inhaler with Attachments for the Administration of the A.C.E. Mixture or Chloroform (Mr. C. C. Braine), 1485

Eight Temperature Charts illustrating Paper on Reactions in Cases of Wounds and Ulcers treated by Oxygen Gas (Mr. G. Stoker), 1545, 1546

Improvements in Crutches, 1558

Nasal Curettes (Dr. G. H. Mackenzie), 1558

New Parallel Expanding Rectal Speculum (Mr. J. MacMunn), 1558

View of the Dental Hospital of London as it will appear when completed, 1573

Various Illustrations accompanying the Morison Lectures on the Relation of the Nervous System to Disease and Disorder in the Viscera: (1) Photoprints showing Nerves from the Body of the Uterus of Pregnant Cats and Nerves in the Apex of a Cat's Heart; and (2) Pulse Tracings under Various Conditions (Dr. A. Morison), 1614, 1690, 1751, 1753, 1754

Seven Full-length Photoprints of Patients, Sketch of Saw, and several Diagrams illustrating paper on the Prevention and Correction o Short Leg in Hip Disease (Mr. R. Jones), 1624, 1625, 1626, 1627

The "Perfect" Hot Appliance, 1643

Atmo-therme Steriliser, 1643

Portrait of the late Sir William Jenner, Bart., 1674

New Form of Warm Dry Air Inhaler (Mr. A. Duke), 1711

The "Association" Vaccinator, 1770

View of a Closet or Privy in Belfast accompanying paper on the Epidemic of Typhoid Fever in Belfast (The Special Commissioner of THE LANCET), 1812

END OF THE SECOND VOLUME FOR 1898.

The Croonian Lectures

ON

THE CHEMICAL PRODUCTS OF PATHOGENIC BACTERIA CONSIDERED WITH SPECIAL REFERENCE TO ENTERIC FEVER.

Delivered before the Royal College of Physicians of London on June 14th, 16th, 21st, and 23rd, 1898,

BY SIDNEY MARTIN, M.D. LOND., F.R.S.,

FELLOW OF THE COLLEGE; PROFESSOR OF PATHOLOGY, UNIVERSITY COLLEGE: AND ASSISTANT PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND TO THE HOSPITAL FOR CONSUMPTION, BROMPTON.

LECTURE III.[1]

Delivered on June 21st.

PRODUCTION OF THE POISONS OF THE TYPHOID BACILLUS IN ARTIFICIAL-CULTURE MEDIA.

MR. PRESIDENT AND GENTLEMEN,—Two different kinds of media were employed in which to grow the bacillus. Ordinary peptone broth was used to determine the presence or not of secretory products of the bacillus and broth containing no peptone but mixed with some proteid solution—either blood serum or alkali albumin made from the spleen or extract of lymphatic gland—in order to determine the presence of digested products of the bacillus. In some cases liquid blood serum sterilised at 60° C. was used without the addition of broth. The virulent bacillus grows well in ordinary peptone broth but the growth in solutions containing much proteid is very much less exuberant. This is especially the case with sterile blood serum and most commonly the bacilli, after growing for a time, sink to the bottom in clumps and cease growing, although they still are alive and active. They grow much better in a solution containing a small proportion of alkali albumin, but still not nearly as well as they do in broth. The object of growing them in the presence of proteids was to test whether there was any digestive action of the bacillus. In one experiment two test tubes were filled about 3 in. deep with liquid blood serum, which was rendered semi-solid by heating at a temperature of from 65° to 70° C. The medium was translucent and one of the tubes was inoculated with the bacillus, the other being kept as a control. It was observed that the bacillus rapidly grew in the medium, spreading through all parts of it, but that no liquefaction indicative of digestion occurred during incubation, which lasted 102 days. When grown in a liquid medium, however, containing a small proportion of alkali albumin, and especially alkali albumin made from splenic pulp, the virulent bacillus has a slight but very insignificant digestive action. Thus in one experiment after the bacillus had grown 32 days in such a medium it was found that the solution gave a distinct biuret reaction with copper sulphate and potash and that the alkali albumin was beginning to be changed into albumoses. This digestive action, although slight, is explanatory of the albumoses found in the spleen in cases of typhoid fever.

Poison formed in proteid solutions.—If the non-virulent bacillus is grown in a solution containing digestible proteid instead of peptone a poison is formed which has an action like that of the poison formed in broth. Thus in one experiment the bacillus was grown in a 1 per cent. solution of serum alkali albumin in broth for 29 days, at the end of which time it was filtered, the filtrate concentrated, and the proteid was separated by alcohol. Some amount of digestion had taken place as the solution gave a biuret reaction. The solid product obtained was injected in two doses (about 0·3 gramme) on successive days into the marginal vein of the ear of a rabbit. There was a marked lowering of the temperature and a subsequent rise following each injection, but not to the average normal temperature of the animal for some days. Some bodily depression was observed on the first two days of the experiment and there was a loss of body weight, but there was no diarrhœa and the animal subsequently completely recovered. In another experiment the non-virulent bacillus was grown in a solution of alkali albumin made from the splenic pulp but without adding broth. One flask was filtered after 45 days and 10 c.c. of the filtrate were injected in two doses on successive days into the marginal vein. After the first injection there was only a very slight rise of temperature which, however, was more marked after the second injection. The animal showed no particular symptoms except a gradual loss of weight, which amounted to 235 grammes at death, on the twenty-eighth day of the experiment. The post-mortem examination revealed no naked eye change in any of the organs or tissues of the body. No cultivations were obtained from the heart's blood; the heart muscle showed no fatty degeneration and there was no degeneration of the peripheral nerves. Another culture was filtered after 59 days' incubation, and 12 c.c. were given in two doses on successive days also into the marginal vein. There was a well-marked rise of temperature after each injection, but no diarrhœa was produced and there was only a slight loss of weight which was recovered from. The animal died in 24 days and no cultivations were obtained from the heart's blood, liver, spleen, or peritoneal cavity. There was subcutaneous hæmorrhage in patches in front of the thighs and in the caudal region, and the peritoneum contained about 1 centimetre of clear fluid. There was no peritonitis and the organs showed no change to the naked eye. The results of growing the non-virulent bacillus in a proteid solution show that the poisons are of the same nature as that formed by the virulent bacillus in broth. The digestion which takes place in the proteid solution is extremely slight and the toxic body is thus mainly a secretion of the micro-organism.

Although the toxic products are developed in the presence of digestible proteids, yet they are most evident when the bacillus is grown in peptone broth. In one experiment the broth was inoculated with the typhoid bacillus obtained from the spleen in a case of enteric fever but before it had been made virulent by passage through animals. The growth was allowed to continue for 11 days, and the broth was filtered through a Chamberland filter. Two injections into the marginal vein were made on successive days. The first injection, of about 3 c.c., resulted in the lowering of the temperature and in the production of diarrhœa soon after the injection. The second injection—also of 3 c.c.—produced but little effect, and on the three subsequent days no appreciable change occurred in the animal. On the sixteenth day of the experiment the animal was found to have lost 170 grammes in weight, and to have some degree of fever, which, however, did not reappear. It lived for 24 days gradually losing weight until at death it had lost 235 grammes. At the post-mortem examination there was no obvious lesion found in any of the organs of the thorax or abdomen, the intestines were normal and cultures made from the heart's blood in the peritoneal cavity were sterile, showing that there was no bacterial infection. The heart-muscle, examined after staining with osmic acid, showed degeneration of most of the fibres, there being loss of striation with longitudinal fibrillation and fatty granules in the muscle cell. This experiment shows several points which will be brought out more fully later: (1) that a poisonous substance is present in the broth apart from the bacillus itself; (2) that this body produces a lowering of temperature and diarrhœa, as well as a loss of weight; and (3) that at death there was distinct degeneration of the cardiac muscle.

The broth culture from the same stock of bacillus was more poisonous and produced a more profound effect if the incubation lasted 25 days. A rabbit received a single dose of 6 c.c. of the broth filtrate after 25 days' growth. The initial effect of this injection into the venous system was a rise of temperature (the maximum being attained in two and a half hours) and a rapid fall, during which there was profuse diarrhœa, with collapse and laboured breathing. This period of depression lasted some hours and was succeeded on the next morning by a febrile rise which continued during the whole of the day. On the following day the temperature was somewhat irregular, but subsequently no great change in the temperature was noticed. The weight fell rapidly up to the fourth day of the experiment, when the animal had lost 120 grammes. Subsequently, however, it regained part of the weight, and at death, on the twenty-sixth day of experiment, the loss was only 35 grammes from the original weight. No naked-eye changes were observed on

[1] Lectures I. and II. were published in THE LANCET of June 18th and 25th, 1898, respectively.

Digitized by Google

post-mortem examination and no cultures were obtained from the organs of the body. The heart-muscle showed slight signs of degeneration.

The more virulent the bacillus the more toxic becomes the broth. Thus, after growing the virulent bacillus for 11 days the micro-organism was killed by chloroform and the broth mixture centrifugalised, the clear broth being used for the injection. Five cubic centimetres were injected in two doses of 2 c.c. and 3 c.c. respectively on successive days. An initial depression of temperature followed by fever was observed after both injections, and the animal died in 12 days with no naked-eye change in the organs of the body, which gave no bacterial growth. There was a very well-marked degeneration of most of the muscle fibres of the heart. These results may be taken to illustrate the action of the clear broth without the bodies of the bacillus—i.e., of the chemical poison which is present in solution in the broth.

Action of broth with the bodies of the bacillus.—The toxic action of the bodies of the bacillus itself was tested by killing the bacillus with chloroform. When the culture was sterile the chloroform was removed *in vacuo* and the liquid used for injection. In one experiment a 13 days' old culture was used and 4 c.c. were injected into the marginal vein of the ear. There was a fall of temperature in two and a half hours, and this low temperature continued the whole of the first day of experiment and also on the second day. On the morning of the third day the mercury of the thermometer would not rise and the animal died. Soon after the injection there was slight diarrhœa. During the subnormal temperature the animal became increasingly weaker, the fur becoming ruffled, although there was no diarrhœa. The loss of weight in the two days of experiment was 180 grammes. There was no naked-eye change in any of the organs and the blood was sterile. This experiment may be taken as showing the profound effects following the injection of the poison. The great depression of temperature, however, observed in this experiment is not the only effect to be produced. In some of the experiments with a weaker poison no depression ensued, but a well-marked rise of temperature; thus 3 c.c. of a broth culture (seven days' growth) killed with chloroform were injected into the marginal vein of the ear of a rabbit. There was a considerable rise of temperature after the injection, which continued during the whole of the following day and the day after. On the fourth day the temperature partly regained the normal limit and continued afterwards normal. There was a loss of weight up to the seventh day after which the animal recovered. In this experiment no diarrhœa was produced and no symptom except that of fever and loss of weight. In two or three other experiments with the broth and the bodies of the bacillus these features were noted, but there was not infrequently an initial fall of temperature, succeeded by a prolonged rise, and diarrhœa for a longer or a shorter period was a fairly constant symptom. There is no doubt, then, that the retention of the dead bodies of the bacillus in the broth renders it more poisonous. The effect on different animals varies somewhat. In the experiment which was mentioned above 4 c.c. took two and a half days to kill. In another experiment 4 c.c. of the same stock caused death with lowering of the temperature in three and a half hours. There is also some individual peculiarity in the animals as regards their resistance against the poison.

The effect of heat.—The effect of high temperature on this poisonous liquid containing the bodies of the bacillus was tested in order to see whether the toxic substances were sensitive to heat or not. In one experiment the broth with the bodies of the bacillus was heated for ten minutes to 60° and 64°C., 4 c.c. were injected into the marginal vein, and death occurred, with lowering of temperature and diarrhœa, in two hours and twenty minutes. This death was more rapid than in the control experiment with the same amount of broth unheated. As marked was the effect of exposing the broth to a higher temperature before injection. 4 c.c. of a broth mixture heated at the boiling point of water for five minutes were injected into the marginal vein and death with profuse mucoid diarrhœa occurred in two and three-quarter hours. This experiment may be compared with a similar one previously mentioned in which the same amount of broth, but unheated, was injected into another animal which lived for two and a half days with great depression of temperature. It may be said, therefore, that this degree of heat not only does not destroy the poison which is in the bodies of the bacillus, but actually brings out its effects. It may be that the heat breaks up the bodies and liberates the poison inside, and after heating some of the bodies of the bacillus may be observed disintegrated under the microscope. There is no evidence from the experiments that there are two kinds of poison, one extra-cellular or secreted by the bacillus and one intra-cellular, with different actions. The toxic properties of the broth from which the bacilli are separated by means of the Chamberland filter are practically the same, although not so pronounced as those observed when the broth contains the bodies of the bacillus as well. This is not an unimportant point, inasmuch as some have made a distinction between the intra-cellular and the extra-cellular poisons of pathogenic micro-organisms. No effect is more marked or more constant in the action of the poison than the production of diarrhœa which with the more active poison is very profuse, lasting a varying time, sometimes hours, sometimes a day, and consists in the passage of liquid motions, with mucus occasionally, but no blood at any time. On a post-mortem examination of an animal dying from this diarrhœa characteristic appearances are almost invariably found. The stomach may be full of undigested food, the cæcum and colon contain liquid fæcal matter, but the greatest change is in the small intestine which is full of a slightly turbid, sticky fluid, containing but little food and no bile. This liquid is simply a solution of mucin, which may be separated by precipitation with acetic acid. The mucous membrane is a little soft on the surface and there is a very large increase in the number of goblet cells. The Peyer's patches are not apparently altered. The changes described by Sanarelli in the Peyer's patches of the intestines have not been observed by me. The loss of weight is also a constant symptom, and the more virulent the poison the more marked it is seen. It is also in these cases progressive. With a smaller dose of the poison, however, the initial loss of weight is regained. No naked-eye change is produced by the poison in the organs of the body. The effect of the poison, when death of the animal is slow, in producing degeneration of the cell fibre of the heart is well marked. The heart was never found in a state of advanced fatty degeneration, but rather in the earlier stage, in which there is loss of transverse striation of the fibre, with the appearances of longitudinal fibrillation and the presence of numerous granules in the fibre, staining more or less black with osmic acid.

BACILLUS ENTERITIDIS (GÄRTNER).

The experiments with this micro-organism were conducted in the same manner as those with the typhoid bacillus. A culture was kindly sent to me by Dr. Durham which gave the reactions previously described as characteristic of the bacillus. It differs from the typhoid bacillus in the fact that it causes gas formation in glucose-agar or glucose-gelatin, but like the typhoid bacillus it does not coagulate milk and it forms but little or no indol in broth. The original culture of the bacillus worked with was toxic, as 5 c.c. of a two days' old broth culture injected into the peritoneum of a guinea-pig killed the animal in less than twenty-four hours. The virulence of this bacillus was increased by passage through animals in a manner similar to that which has been described with regard to the typhoid bacillus—that is, some of the peritoneal exudation from the first animal which died being injected into the peritoneal cavity of a second guinea-pig, and from the second into a third and so on. The death of each animal occurred as a rule in less than twenty-four hours The dose was gradually lessened until a small loopful of an agar culture injected into the peritoneal cavity killed the animal. In the series of experiments the intra-peritoneal injections caused the exudation of a highly albuminous fluid containing numbers of bacilli. In the earlier cases there was also an exudation of leucocytes; later on, however, these disappeared. Occasionally there were a few flakes of lymph on the surface of the peritoneum, but only at the early stage of the series of inoculations. At no time was there any exudation of blood. During the series cultivations were made from the peritoneal fluid of each animal to test the purity of the growth, to see whether the bacillus kept its characteristics, and also to study the distribution of the micro-organism in the body. It was seen that the growth was always typical and pure, and that when the bacillus became virulent it was found always distributed throughout the organs of the body, being obtained from the heart's blood, the spleen, the liver, and the kidneys and peritoneal cavity in pure cultivation. In this

Digitized by Google

respect the presence of the bacillus of Gärtner in the various organs of the body is more constant than that of the typhoid bacillus.

The peritoneal fluid was highly toxic. Thus in one experiment in which the bacilli were killed by means of chloroform and removed by subsequent centrifugalising, 3 c.c. of clear peritoneal fluid injected into the marginal vein of a rabbit weighing 470 grammes caused death in one and a half hours, the temperature rapidly falling in half an hour from 102° to 97·4°. The peritoneal fluid filtered through porcelain is not so toxic as the unfiltered fluid from which the bacilli have been removed by centrifugalising. This filtered peritoneal fluid was found to produce fever when injected into the marginal vein of the ear of the rabbit, but when given in two doses of 1·5 c.c. and 1 c.c. it did not cause the death of the animal nor any particular symptoms except a rise of body temperature.

Growth of the bacillus in broth.—The experiments performed in this way were precisely similar to those with the typhoid bacillus. The virulent Gärtner bacillus was grown in broth for 22 days and the culture was not filtered, but the bacillus was killed by chloroform. Experiments were performed with the clear broth after centrifugalising and with the turbid broth—that is, with the broth plus the bodies of the bacilli. Each animal received the same dose—viz., a single dose of 4 c.c. into the marginal vein. The result of the injection of the clear broth was a continued and marked depression of temperature during the day of experiment, the temperature next day again rising to normal. There was diarrhœa soon after the injection of the poison and there was a progressive loss of weight. A similar dose of the broth, plus the bodies of the bacilli, caused a more marked depression of temperature which lasted till the following morning and most of the following day. Here also there was diarrhœa and a progressive loss of weight. The effect of heat on the broth containing the bodies is seen in the two following experiments. Thus the same dose (4 cc. of the mixture) heated to 60° C. for ten minutes caused a depression of temperature which was very great and ended in death in four and a half hours. This animal also showed diarrhœa. A similar dose heated to 100° C. for ten minutes produced also a very great depression of temperature which lasted to some extent till the next day. There was well-marked diarrhœa and great loss of weight. It is thus seen that the characteristic action of the toxic products of the Gärtner bacillus is very like those of the typhoid bacillus. There is present in the broth from which the bacilli have been removed a poison which causes a great depression of temperature, and this poison is also present in the bodies of the bacillus and has an action similar to that of the poison obtained from the typhoid bacillus—viz., it produces diarrhœa and loss of weight. Like the poison of the typhoid bacillus, the virulence of a broth culture containing the bodies of the bacillus is increased by heating the solution at 60° C., so that, as seen in the experiments just quoted, whereas 4 c.c. of the unheated mixture did not cause death, when it was heated to 60° for ten minutes death occurred in 3½ hours with great lowering of the body temperature. The mixture heated to 100° C. for the same time gives a greater effect than the non-heated mixture, but does not produce death in the same day as when the mixture is heated to only 60° C. The effect of heat appears to be to break up the bodies of the bacillus so that the poison is liberated, making the liquid more toxic. When grown in a proteid solution containing alkali albumin or serum proteids Gärtner's bacillus causes some amount of digestion with the formation of albumoses. This is more marked than is the case with the typhoid bacillus, although the digestion is still far behind that which occurs in the case of the bacillus diphtheriæ and the anthrax bacillus. One result obtained is interesting inasmuch as the bacillus coli also produces it—viz., that when grown in Marmorek's fluid Gärtner's bacillus produces a partial precipitation of the proteid solution in the form of a gelatinous clot. In strong solutions containing serum this result, however, was not observed and it was not so constant as with the bacillus coli.

BACILLUS COLI COMMUNIS.

There is one important difference between this bacillus and the two other forms we have considered (the typhoid and Gärtner bacillus). This is the fact that it is one of the causes of putrefaction of proteids. It forms indol, for example, in proteid solutions; it is found in foul water, in soil, and it is a constant inhabitant of the intestines, being found in that region soon after birth. After death it sometimes penetrates the different abdominal organs and is one of the causes of the putrefaction of the body. These characteristics, therefore, mark it sharply off from the two other micro-organisms. There are, no doubt, many different forms of the bacillus coli which differ in minute particulars, some, for example, forming hardly any indol, others coagulating milk slowly. Without however, entering into the different forms which this bacillus may assume or into a discussion as to whether they are all modifications of the same form I may say that the bacillus I worked with was one which was obtained from the spleen in a case of typhoid fever and which no doubt came originally from the intestinal tract. The virulence of the bacillus coli as obtained from the intestines varies considerably and several observers have described an exaltation and an increase in the numbers of the bacillus in the course of cases of typhoid fever. The bacillus I obtained from the spleen was more virulent than the stock cultures of the bacillus which I had in the laboratory and which were obtained from different sources. Its virulence was readily increased, much more readily than that of the typhoid bacillus or of Gärtner's bacillus. 6 c.c. of a fourteen days' old broth culture injected into the peritoneal cavity of a large guinea-pig caused death in under twenty-four hours; 4 c.c. of a broth culture of the peritoneal exudation of the first guinea-pig was injected into the peritoneal cavity of a second and killed the animal in under twenty-four hours. In the succeeding experiments 2 c.c. of the peritoneal fluid were found to kill; 0·5 c.c. was fatal at the fifth inoculation and at the sixth it was found that 0·25 c.c. and 0·1 c.c. killed the animals in four hours. At this stage the virulence of the bacillus was considered sufficiently exalted for experiments to be performed. Throughout, the cultures obtained from the peritoneal fluid were pure and always gave the typical reactions of the bacillus coli. The results of the injection of the bacillus into the peritoneal cavity differed markedly from those obtained from the injection of the other two bacilli, mainly in the fact that the effusion was blood-stained, more so at first than later, when the bacillus became more virulent. The blood-staining was not due to the exudation of corpuscles but to the colouring matter of the blood being dissolved in the liquid, which was highly albuminous. Numerous petechiæ were also observed, both beneath the peritoneum and the mucous membrane of the ileo-cæcal region and cæcum. No peritonitis was observed at any time. The toxic products of the bacillus were investigated by growing it in broth and in proteid solutions.

Growth of the bacillus in broth.—An early experiment was performed with the bacillus which was not extremely virulent and which was grown in broth for twenty-three days. The broth was then filtered through a Chamberland filter and 8 c.c. of the sterile filtrate were injected in two doses on successive days into the marginal vein of the ear of a rabbit weighing 1090 grammes. The initial effect of the first injection was a fall of temperature in about two hours which lasted over four hours, the total fall of temperature being 5° F. The result of the second injection on the following day was practically *nil*, but on the third day the temperature was subnormal. It then began to rise gradually and there was some degree of fever on the fifth, sixth, and eighth days of experiment, which was markedly increased on the ninth day. On the tenth day there was a fall and a subsequent rise on the eleventh day, after which the temperature of the animal became practically normal. The animal steadily lost weight during the first two days of experiment—100 grammes the first day and 38 grammes the second day, the weight remaining stationary on the third, fourth, and fifth days of experiment, after which it slowly regained its normal. The animal exhibited no other symptom; there was no diarrhœa and complete recovery took place. This result shows that the poisonous products which are formed in the broth by the bacillus coli have the initial effect of reducing the temperature of the body as well as weight and that subsequently there is a reactionary rise of temperature, which remains at a febrile point for several days.

Other experiments were done with the broth cultures in the same way as those done with the typhoid bacillus and with Gärtner's bacillus—viz., after a period of 18 days' incubation the bacilli were killed with chloroform and the injection of the clear broth obtained by centrifugalising and

Digitized by Google

of the broth with the bodies of the bacilli was performed in different animals. In the first experiment 4 c.c. of clear broth were injected into the marginal vein of a rabbit weighing 720 grammes. In 2½ hours the temperature had fallen 2° and there was slight diarrhœa. In 4½ hours there was a further fall of 2·5° and the temperature altogether remained subnormal for over five hours. On the next day it had regained its normal limit, though the animal continued to lose weight. In the second animal a similar dose of 4 c.c. of the broth containing the bodies of the bacillus were injected into the marginal vein. The temperature fell about 1·5° in two and a half hours, after which it began to rise slightly, and during the whole of the next day the temperature of the animal was febrile. In one and a half hours after the injection there was slight diarrhœa and the animal lost 70 grammes in twenty-four hours. The temperature remained at about the normal level till the fifth day. On the seventh day it had fallen and there was slight diarrhœa. On the eighth day there was a fall to 98° F. and on the ninth day when death occurred the temperature was below 95°. The total loss of weight was 210 grammes. These results were compared with the results of injecting a similar dose of the same stock of broth containing the bodies of the bacillus but which had been subjected to heat. In the first of these experiments the mixture of broth and bodies was heated at 60° C. for ten minutes. The result of the injection was the cause in a very short time of a febrile rise of temperature which lasted the whole of the day and was present in the morning of the following day, the temperature then gradually falling to the normal. In one and a quarter hours after the injection there was profuse diarrhœa and the animal lost somewhat in weight during the first two days of experiment. In another experiment a similar dose was given after being heated to the boiling point of water for ten minutes. In less than an hour after the injection profuse diarrhœa was observed and the temperature rapidly fell, the total fall being 7° F. The animal died in six hours.

It is seen from these experiments that the clear broth—that is, the broth not containing the bodies of the bacillus—produces a fall of temperature and loss of weight with some diarrhœa and that a similar dose of the broth with the bodies of the bacillus causes some lowering of temperature and a reactionary febrile rise and that the effect of heating the mixture of broth with the bodies of the bacillus is to increase the poisonous activity of the solution, so that when the mixture was heated to 100° C. it proved fatal to the animal in six hours with great lowering of temperature. The explanation of this appears to be that the action of the heat causes the discharge of the poison which is present in the bodies of the bacillus. 1. The type of action of the poison of the bacillus coli appears to be the same as that of the other two bacilli investigated, in some cases producing a great fall of temperature and in other cases a rise of temperature. 2. Heating the dead bodies of the bacillus suspended in the broth culture fluid increases the toxicity of the solution, as in the case of the two other bacilli, but in the case of the bacillus coli it requires a temperature of the boiling point of water to effect this, whereas with the other two micro-organisms such a temperature rather diminishes than increases the toxic action. Altogether, the mode of action of the poisonous products of the bacillus coli is more irregular than with the other two bacilli, not only as regards its lethal but also as regards the irregular kind of fever and after-fever produced.

Growth of the bacillus in proteid solutions.—As with the other bacilli, very different forms of proteid solution were used as culture medium—liquid serum, serum diluted with salt solution, serum diluted with broth, alkali albumin in broth, and Marmorek's fluid. The general result obtained in these culture media was that the bacillus coli digested the proteids present and produced an abundance of albumoses (a much greater quantity than the typhoid bacillus and Gärtner's bacillus), so that at the end of a month's incubation of such a culture a brilliant biuret reaction was obtained. The digestion of proteids by the bacillus coli is not nearly so marked as it is with the anthrax bacillus or the diphtheria bacillus. A more remarkable effect was observed in the fact that after the bacillus had been growing in a proteid solution for some time it precipitated the proteid in the form of a clot, and this occurred more particularly in the solutions of diluted serum and in Marmorek's fluid. The results were compared with a control flask which was not inoculated and which was kept in the incubator alongside the cultures. The precipitation of the proteid in the form of a gelatinous clot was not constant although it occurred in the majority of cases. It did not appear to be due to any increased acidity of the culture medium produced by the growth of the bacillus in it, inasmuch as no such increase of acidity was present, the liquid remaining alkaline. The phenomenon appears to be a special action of the growth of the bacillus coli. In some solutions Gärtner's bacillus produced the same result. Thus five flasks were prepared containing about 100 c.c. of Marmorek's fluid, which is a mixture of one part of ascitic fluid with two parts of broth. Two flasks were inoculated with the bacillus coli, two were inoculated with Gärtner's bacillus, and one was kept as a control. In fourteen days a copious and soft clot had formed at the bottom of all the four flasks, the liquid in the control flask remaining limpid and unclotted. In none of the similar experiments with the typhoid bacillus was any clot or precipitation of the proteid observed, so that this serves as another distinction between the typhoid bacillus and the two other bacilli. The clotting of the proteid solution is of interest in connexion with the experiments of Stillmark, who found that the substance called ricin, which is obtained from the seeds of the castor-oil plant and which will be discussed later, also produces a clotting in proteid solutions, especially serum. Stillmark used it as an argument in favour of the ferment nature of the toxic body, ricin.

THE RELATIONSHIP OF SOME FORMS OF COMBINED DEGENERATIONS OF THE SPINAL CORD TO ONE ANOTHER AND TO ANÆMIA.

BY J. S. RISIEN RUSSELL, M.D. EDIN., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND PATHOLOGIST TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE.

INTRODUCTION.

THOUGH the writings of Lichtheim[1] ten years ago first called general attention to the association of symptoms indicating affection of the spinal cord with those of pernicious anæmia, Leichtenstern[2] in 1884 described two cases of what was evidently the same condition, as tabes associated with anæmia. During the decade which has elapsed since Lichtheim's first paper many important communications on the subject have been made which have greatly advanced our knowledge not only of the clinical characteristics of this affection of the spinal cord but also in regard to its etiology and pathology. Among the earlier contributions to the subject two emanated from the National Hospital for the Paralysed and Epileptic, the first by Dr. H. M. Bowman,[3] whose promising career was so early terminated by death, and the second by Dr. James Taylor,[4] whose important communication holds a leading place in the history of the disease. I feel it in a measure my duty, therefore, to record our further experience of the affection at the hospital since the second of these papers appeared in 1895, and I am greatly indebted to Dr. Charlton Bastian, Sir William Gowers, and Dr. Ferrier for allowing me to make use of the cases which form the subject of the present communication. Although a large number of papers have appeared on the subject of the changes found in the spinal cord in cases of pronounced anæmia, and although a few writers have suggested a possible connexion between this condition and that described by Gowers under the title of ataxic paraplegia, no serious attempt has been made to discuss the relationship fully or to establish a connexion between the two affections, if we except an important paper by Rothmann[5] which deals with the whole subject of the primary combined tract affections of the spinal cord. Besides presenting other features of interest the following cases appear to me to afford a good opportunity of discussing

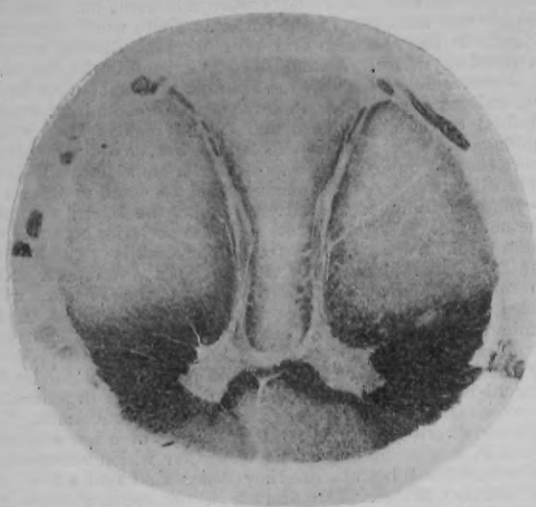
the possibility of such a relationship with a reasonable prospect of adding to our knowledge on this subject. I propose therefore to relate briefly the clinical histories of the three cases, to deal much more fully with the morbid changes met with in the spinal cords post mortem, to discuss the etiology and pathology of these and similar cases, and finally to adduce reasons for considering that the affection is the same as that which has been described as ataxic paraplegia.

CASE 1.—A married woman, aged forty-four years, was admitted into the National Hospital for the Paralysed and Epileptic on May 11th, 1896, under the care of Dr. Bastian, complaining of loss of power and impairment of sensation in both inferior extremities and the right hand, violent intermittent pain in the stomach and chest, and loss of control over the sphincters. A brother, aged thirty-two years, is the subject of locomotor ataxy, two sisters died in youth from concussion of the brain, and a third from convulsions when teething. She had had seven children, of whom two had died within twenty-four hours of birth, and a third at the age of thirteen months from (?) rickets. She had been a teetotaler for thirty years. Thirteen years before her admission she suffered from a severe hæmorrhage after a confinement and had never regained her strength since. Her catamenia had been regular until the last two or three years when it had become very scanty. She had never had miscarriages and there was no history of syphilis. About a year before she came into hospital she began to suffer from tingling and numbness of her hands and feet, which lasted for two months and then passed off. Since Christmas, 1895, she had gradually become weaker, with shortness of breath on exertion, and about the end of January she began to be clumsy in the use of her feet. She took to her bed in the middle of February and about the end of that month, when she tried to get up, she found that she could not stand. About the beginning of March she began to suffer from cramps in her legs, which at the time of her admission were almost constant when she was awake. She suffered from constipation for a time and this was followed by diarrhœa a week ago, since which the motions had been passed involuntarily. A day or two before she came under observation she noticed some difficulty in using the right hand, which became numb and began to tingle. On admission she was found to be emaciated, her skin and mucous membranes were very pale, and there was marked œdema of her ankles, feet and tissues over the sacrum. She was only able to move her lower extremities feebly and was much troubled by twitchings and cramps, the latter extending up into the abdomen. The power of movement of the right arm was also impaired. The muscles of the limbs were much wasted, but no tenderness was elicited on pressure. There was partial loss of sensibility of the lower extremities and right arm, and she was not often able to detect touches on the right side of the trunk. Painful impressions were not felt on the legs and thighs and there was an inability to appreciate heat and cold below the level of the umbilicus on the right side and below the pelvis on the left. The knee-jerks were brisk, there was ankle clonus on both sides, and the plantar reflexes were very brisk. There was absolute incontinence of urine and fæces, with inability to feel when the evacuations were passing. There were no cerebral symptoms and the cranial nerves were intact. Hæmic murmurs were heard over the precordia and in the neck. Hæmoglobin was 28 per cent., the red cells were much diminished, and nucleated red cells were present in relatively large numbers. The pulse was 78, the respiration was 16, the morning temperature was 98·6° F. and the evening temperature was 99°. Subsequently the knee-jerks became abolished, there was œdema of the conjunctivæ, diarrhœa set in, she developed a bedsore on the sacrum, began to be delirious, and eventually died on June 11th, 1896—i.e., one month after admission, and a little more than a year from the commencement of her illness.



Necropsy.—I made the post-mortem examination nineteen hours after death and found the body extremely emaciated, of a yellowish-white colour, with no abnormal pigmentation, and with œdema of the lower part of the back, ankles, and feet, and a large bedsore on the sacrum. The subcutaneous fat was exceedingly small in amount and the marrow of the long bones was natural. The skull and dura mater were natural, but the cerebral convolutions were shrunken, with compensatory œdema of the pia-arachnoid. The brain was otherwise natural on macroscopic examination, as were the cerebellum, pons, and medulla. The cranial nerves were natural and there were no retinal hæmorrhages. The bones and meninges of the spinal canal were natural, as was the appearance of the spinal cord even on section, no sclerosis or other change being obvious to the unaided eye in the fresh condition. There was a slight excess of bright yellow clear fluid in the pericardium; the left pleural cavity contained about half a pint and the right a few ounces of similar fluid. There was no tabby striation of the heart and there were no hæmorrhages anywhere. Both lungs were emphysematous, with œdema and hypostatic congestion more pronounced on the right side. The liver was slightly fatty and did not give the iron reaction. The spleen was natural; the capsules and the kidneys were adherent, but there was no obvious reduction of the cortex. There were no enlarged glands in the abdomen and no malignant disease was discovered anywhere. A small fibroma existed in the uterus.

Microscopic examination.—The changes met with in the central nervous system on microscopical examination were limited to the spinal cord and caudal part of the medulla oblongata. The regions affected in the medulla oblongata were those occupied by the posterior columns and the direct cerebellar tracts, but the degeneration appeared to extend far beyond the limits of the latter tract in the lateral region of the medulla. The degeneration in the posterior columns was more pronounced in the funiculus gracilis than in the funiculus cuneatus, and the cells of both were intact. Next to no recent degeneration existed in the former, while there was considerable degeneration of this kind in the funiculus cuneatus and direct cerebellar tracts. The restiform body showed no obvious change in sections prepared by the Pal-Weigert method, but in those prepared by the Marchi method an extensive amount of recent degeneration was seen in these structures passing to the cerebellum. The pyramids were intact with the exception of a few scattered fibres in a recent state of degeneration which were seen in these structures both before they decussated and among the decussating fibres. The arcuate fibres passing from the posterior column nuclei were intact and the emergent fibres of the hypoglossal nerves showed no degeneration, though there was marked pigmentation of the cells of their nuclei. The essential changes in the spinal cord consisted in a degeneration of the nerve elements, thickening of the neuroglia, and marked vascular changes. In the cervical region of the cord the degeneration was most pronounced in the postero-internal columns and the cornu commissural and posterior root zones on both sides. Some of the postero-external column was preserved, though there were only scattered fibres, the degeneration being very marked even in this part of the posterior columns. A band of healthy fibres, however, separated the grey matter from the more altered parts of the posterior columns, this being especially well marked at the cornu commissural region and posterior horn; but even in these parts there were many fibres in a recent state of degeneration. Indeed, the fibres showing early degenerative changes were more numerous in these better preserved parts of the posterior columns, and in the areas bordering on them, rather than in parts where the degenerative changes were more pronounced and obviously of longer standing. The lateral region of the spinal cord on each side was similarly affected to the posterior columns; here diffuse degenerative changes existed in both crossed pyramidal tracts and in the direct cerebellar and posterior part of the antero-lateral ascending tracts. Healthy fibres in the lateral limiting layer separated the grey matter from the profoundly altered lateral columns, but even among these fibres there were many in a recent state of degeneration, a condition which, as in the posterior columns, was most marked in the areas of junction between the obviously pronouncedly degenerated and the apparently healthy fibres of this part of the cord. There was marked degeneration of one direct pyramidal tract and slight of the other; there were also two islets of degeneration in the region of the ground bundles on the side of the more affected direct pyramidal tract, and one small islet in the position of the anterior part of the ascending antero-lateral tract a little ventral to the anterior horn. The precise degree of degeneration and its distribution varied at different levels; thus sections from another part of the cervical cord showed only slight affection of the direct pyramidal tracts, though the one was more affected than the other, as was the case in the other section described; but the islets of degeneration in the ground bundles only existed on the side of the more affected direct pyramidal tract. In the thoracic region of the cord, as in the cervical, the precise distribution of the degeneration varied but the main characteristics were

Digitized by Google

constant (see Fig. 1). Thus there was marked degeneration of the posterior columns with a zone of healthy fibres separating the degenerated areas from the grey matter. Intermingled with the healthy fibres were many in a state of recent degeneration, this being markedly the case in the cornu-commissural zone also. The degeneration in the lateral region of the cord occupied the crossed pyramidal and direct cerebellar tracts, and in the lateral limiting layer where the fibres were in the

FIG. 1.

Transverse section of the thoracic region of the spinal cord in Case 1.

main preserved there were many in a condition of recent degeneration, a state of things common to the margins of all the areas of healthy fibres bordering on the pronouncedly degenerated parts. In the anterior columns the morbid change extended beyond the confines of the ventral portion of the direct pyramidal tract on each side and to a lesser degree on one side in that part of the tract immediately ventral to the anterior commissure, while this part of the direct tract

FIG. 2.

Transverse section of the lumbar region of the spinal cord in Case 1.

on the opposite side was free from any change. In no part of the transverse area of the cord did the distribution of the degeneration vary so much as in its ventral portion; thus in other sections from the thoracic cord while the amount of change was different in the two anterior columns as before, in neither was that part of the tract immediately ventral to the anterior commissure affected. In other sections, again, not only the ventral portions of the direct pyramidal tracts were degenerated, but also the antero-lateral margin of the cord and the ground bundles to a point opposite the outer limit of the anterior horn.

In the lumbar cord (see Fig. 2) the postero-internal column was markedly degenerated with the exception of that part of it occupied by fibres of the septo-marginal tract and the fibres of the cornu-commissural zone, both of which had escaped. A marginal area of healthy fibres also existed in the dorsal portion of the posterior columns, but was less marked in the postero-internal than in the postero-external column, considerable portions of other parts of which tract had also escaped. A wide band of healthy fibres separated the grey matter from the more altered parts of the postero-external tract. Fibres in a state of recent degeneration existed in fair numbers in all parts of the posterior columns except the most changed parts of the postero-internal tracts. Such fibres undergoing degeneration were evident in the septo-marginal tracts, but were less so in the band of healthy fibres bordering on the grey matter, while the cornu-commissural zone had escaped in great part even from such early degeneration. In the lateral region of the cord the degeneration was limited to the crossed pyramidal tracts, all parts of the transverse area of the cord ventral to this being free from degeneration, with the exception of the tip of the anterior column on one side where it abutted on the anterior fissure; here there was slight degeneration. A considerable number of recently degenerated fibres existed in the crossed pyramidal tracts, and some in the ventral part of the direct tract, which showed no obvious change when treated by the Pal-Weigert method. There was also a considerable amount of recent degeneration present in the apparently healthy parts of both direct tracts, but more marked on one side than on the other. Similar variations were met with as in other regions of the cord; thus the degree of affection of the cornu-commissural zone was more marked in some sections than in others; the amount of the septo-marginal tract which escaped also varied as did the degree of affection of the ventral tip of the anterior column. The lower lumbar region of the cord was the seat of pronounced degeneration of the posterior columns, though this was not complete in any part of them, healthy fibres being scattered among the degenerated. There were, however, certain parts of these columns which had largely escaped degeneration, an occasional degenerate fibre being alone found in them; these areas comprised the cornu-commissural zone, the septo-marginal tract, the external part of the posterior columns bordering on the grey matter of the posterior horn, the posterior root zone, and a very narrow band of fibres extending along the periphery of the dorsal part of the posterior columns except that part of them close to the posterior median septum. Only a few scattered degenerated fibres were seen in the lateral columns and in the antero-lateral region of the cord. The lower sacral region was free from degeneration with the exception of a few scattered fibres in the posterior columns, while the upper part of this region was similarly spared with the exception of a few small areas of degeneration in the posterior columns. On both sides there was a limited area of such degeneration abutting on the inner border of the posterior root zone and a more pronounced band occupying the dorsal third of the posterior column on one side, situated a little internal to a line which, if extended to this region of the columns, would represent the inner border of the gelatinous substance of Rolando and a similar, though less extensive, band than the last, situated in the ventral half of the dorsal fifth of the posterior columns, close to the posterior median septum, from which it was separated by an area of normal fibres no broader than the degenerated band itself. A degenerate fibre here and there in other regions of the transverse area of the sacral cord was all that was to be seen. The neuroglia was much thickened in the affected areas of white matter. The vessels had thickened walls and were engorged, these conditions characterising both those in the affected areas of white matter and in the grey. In the sacral region of the cord, where the degeneration of the white matter was so limited in distribution, the thickening of the neuroglia was equally limited and vascular changes were by no means conspicuous. Though some of the vessel walls were thickened there was little engorgement and no obvious increase in the number of vessels in the grey or white matter. The nerve cells of the anterior horns were scarce in most parts of the cord

Digitized by Google

and of those present many were obviously atrophied and others though of good size stained badly. These cells were better preserved in the sacral region of the cord than elsewhere, but even here some groups were wanting and others showed evidences of atrophy. In sections prepared by the Marchi method the anterior horn cells throughout the cord were characterised by marked pigmentation and granularity, a condition of things also seen in the cells of Clarke's columns.

Remarks.—We have in this case a typical example of the spinal cord changes which have been described as occurring in association with pernicious anæmia. Clinically the case conformed to this type and the results of the microscopical examination are strictly in accord with those which are regarded as characteristic of this affection. The case, however, serves to emphasise what has already been shown by certain previous observations—viz., that such changes in the spinal cord and their resulting symptoms may occur in all forms of profound anæmia even though they do not conform absolutely, either clinically or as regards the changes found post mortem, to the rules laid down for the diagnosis of the so-called pernicious variety of anæmia. Thus among other signs wanting in this case were the absence of retinal or other hæmorrhages (apart from those in the spinal cord), the normal condition of the marrow of the long bones, and the failure of the liver to give the iron reaction. The special features which call for comment as regards the changes found in the spinal cord on microscopical examination, in that they have not been constantly met with in all cases of the kind previously recorded, are the changes in the grey matter, there being both altered condition of some of the cells and the existence of small hæmorrhages. It is also worthy of note that no hæmorrhages or the remains of these were met with in the white matter, where the degenerative changes of the nerve elements are so pronounced, and that small areas of degeneration in otherwise healthy parts occur quite independently of the presence of any vessel with altered walls in their neighbourhood. One other point alone calls for comment in this case and that is that in the lower lumbar and sacral regions of the cord the posterior columns are almost exclusively affected. This is not a little curious when we remember how profoundly affected the lateral and antero-lateral tracts were in other regions of the cord, for with such affection of these tracts we are at least justified in expecting to find evidences of descending degeneration in the crossed pyramidal tracts and the efferent antero-lateral tracts, including the direct pyramidal, instead of which there is no evidence of such degeneration, an occasional degenerated fibre being alone found in these tracts in the lower lumbar and the sacral regions of the cord.

CASE 2.—A man, aged fifty-three years, was admitted to the National Hospital for the Paralysed and Epileptic under the care of Dr. Ferrier, on Oct. 16th, 1896, complaining of inability to walk, difficulty in commencing the act of micturition, and girdle sensation. His father died from "consumption of the bowels" and his mother had been paraplegic for five years, the condition having been gradual in onset. A sister had died from phthisis, another from dropsy, and a third with wasting. The patient had been much exposed to wet and cold. Twenty years before his admission to the hospital he suffered from gleet, but never had a sore. He had always been temperate. At the age of twenty-six years he had pains in his calves for three or four days and then woke up one morning quite blind and unable to sit up or move his head, arms, or legs. He could swallow and had no difficulty in passing urine. His limbs were flaccid. By the end of the same day he could move his head and by the end of the second day could see with his left eye and was practically well, except that he could not see with the right eye and was unable to stand for about seven weeks. After this he got quite well, though blind in the right eye, and remained so until a year and nine months before he came under observation, when he began to notice that he was unable to bear the heat of a fire on his legs. The bedclothes and the lining of his trousers felt damp, whereas in reality they were quite dry. These subjective feelings at first got worse and then disappeared about seven months ago; but at this time he had a sensation as if walking on wool, his legs became uncertain in their movements, and he had to use sticks in walking. His walking had become gradually worse and he had been quite unable to do so at all for three months. A month before this he developed a girdle sensation which had persisted and at the same time micturition became precipitate. On admission he was found to be the subject of advanced spastic paraplegia. Both legs were extremely stiff, but he could lift them off the bed, could flex and extend at the hip fairly, and he could draw up the legs and move the toes and feet at the ankles well. By far the weakest movement was flexion at the knees. The left leg was possibly slightly the stronger. A girdle sensation was present and there was some pain complained of in the lower dorsal and lumbar regions of the back. There was slight blunting of sensibility for tactile and painful impressions up to the level of the umbilicus. The knee-jerks were increased but there was no ankle clonus. The arms were normal. There was divergent strabismus of the right eye due to blindness from simple optic atrophy, there being only just perception of light with this eye and the pupil only just reacting to light. The ocular movements were normal, there was no nystagmus, and the other cranial nerves were intact. About five weeks later he was much weaker and apparently very anæmic; he suffered a great deal from pain about the lower ribs and in the abdomen, and there was almost complete retention of urine. The great rigidity of the inferior extremities had now altogether disappeared, the limbs became flaccid at all the joints, and there was slight wasting of the calves and thighs on both sides, with great diminution of Faradaic irritability of the muscles of the buttocks, thighs, and legs. To galvanism K.C.C. > A.C.C. The knee-jerks were completely absent, there was no ankle clonus, the plantar and cremasteric reflexes could not be obtained, and the reflex of the sphincter ani was also absent. The epigastric and abdominal reflexes were, however, present. There was complete loss of sensibility for touch and pain up to the knees and marked impairment to two inches above the groins. The skin over the buttocks and sacrum became acutely inflamed, with superficial points of ulceration. The heart was dilated and a slight systolic murmur was heard at its apex. The temperature was 100·4° F. Two days after this he was slightly weaker and the temperature was subnormal, but the bedsore was slightly better. Four days later he died.

Necropsy.—I made the post-mortem examination nine hours after death and found the bones of the skull natural but the dura mater unduly adherent to the inner surface of the skull-cap. The pia-arachnoid presented old patches of thickening, but the convolutions were natural, as were the rest of the brain, the cerebellum, pons, and medulla oblongata, on macroscopic examination. All the cranial nerves appeared natural with the exception of the right optic nerve, which was much atrophied and grey in colour. The spinal canal was natural, as were the meninges and cord, both on external examination and on section. No sclerosis or other defect was evident to the unaided eye in the fresh state. The heart was dilated, the lower lobes of the lungs were in a condition of hypostatic congestion, with old caseous and pleuritic thickening with adhesions at the apex of the right lung. The abdominal viscera were natural, with the exception of very slight adhesion of the capsules of the kidneys, without any obvious reduction in the width of the cortex, and there was hæmorrhagic cystitis.

Microscopical examination.—Subsequent microscopical examination of the central nervous system revealed the following changes. In the medulla oblongata the degenerations were limited to the caudal end. There was pronounced degeneration of the fibres of the funiculus gracilis and cuneatus, the cells of which were intact, as were the emergent arciform fibres. The lateral region of the medulla occupied by the direct cerebellar tract was greatly altered, and extending dorsally and ventrally along the margin of the medulla from the most changed part were a few scattered degenerate fibres with a little patch of them opposite the commencement of the anterior horn on one side and a larger patch just external to the pyramid on the opposite side. There was some degeneration in both pyramids at the level of the decussation; in one it was the part bordering on the anterior median fissure which was chiefly affected, while in the other there were two patches of degeneration separated from each other and from the anterior median fissure by healthy fibres. Degenerated fibres could also be seen among those decussating. Some small foci of degeneration and scattered altered fibres were present in the pyramids for a short distance above the decussation; otherwise the medulla was free from obvious change after the upper limits of the funiculus gracilis and cuneatus were reached and after the direct cerebellar tract had passed into the restiform body. In the

Digitized by Google

cervical region of the spinal cord there was marked degeneration of the postero-internal columns, having all the appearance of being complete, as seen with a low power lens, and separated from the degenerated part of the postero-external column by a narrow band of more or less normal fibres. The postero-external column was much less degenerated and only about the inner half of the tract was affected, the outer part bordering on the grey matter of the posterior horn being preserved. There was, however, a limited area of this outer zone of the postero-external column which was profoundly degenerated near the periphery of the cord in the region of the posterior root zone. The cornu-commissural zone was fairly preserved, but in this as well as in the best preserved parts of the postero-external column many degenerate fibres and spaces from which such swollen degenerate fibres had evidently fallen out were to be seen. The direct cerebellar tract on one side was considerably degenerated about its middle, while the ventral portion was less altered. Dorsal to the more altered part was a less degenerate area, while immediately external to the posterior root was an area of more intense degeneration at the periphery of the cord. On the other side of the cord the ventral part of the direct cerebellar tract was most altered, the middle less so, while the dorsal part of it was as much affected as was the area immediately external to the posterior root. There was degeneration of a patchy and scattered character in the crossed pyramidal tracts; this was less evident in the deeper parts of these tracts and the lateral limiting layer was in the main well preserved. Both direct pyramidal tracts were markedly degenerated in their ventral two-thirds, while only isolated degenerate fibres were dotted about in the portion of the tract immediately ventral to the anterior commissure. The degeneration overstepped the limits of these tracts and extended into the ground bundles and antero-lateral descending tract region at the periphery of the cord; but in both these regions the degeneration outside the area of the direct pyramidal tracts was in the shape of scattered fibres rather than of any compact cluster of these. A few minute islets of scattered degenerate fibres were also seen at the periphery of the cord to about midway between this and the grey matter of the anterior horn.

In the thoracic cord (see Fig. 3) the postero-external

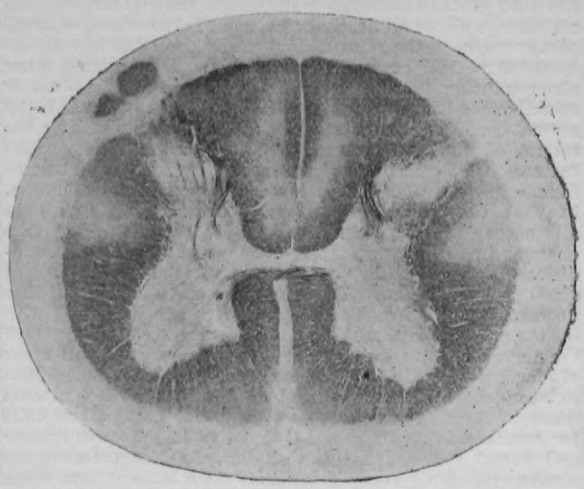


FIG. 3.

Transverse section of the thoracic region of the spinal cord in Case 2.

and internal columns were more equally affected, and the degeneration was less pronounced than it was in the latter tract in the cervical region, being, indeed, more comparable to that seen in the former tract in that region of the cord. Very little of the cornu-commissural zone was preserved at the ventral extremity of the postero-internal column, but at the dorsal end of the tract at the periphery of the cord was a small zone of more or less healthy fibres. A similar condition existed to a lesser degree in the contiguous part of the postero-external column, the whole of the outer half of which tract was also preserved, with the exception of the posterior root zone which was markedly degenerated. The change in the direct cerebellar tracts was considerable, and the crossed pyramidal tracts were more profoundly altered than in the cervical region of the cord, the degeneration being rather more extensive in area on one side than on the other. The lateral limiting layer was fairly preserved. There was marked degeneration of the ventral three-fourths of the direct pyramidal tracts and degenerate fibres in the other fourth, more especially on one side. An extensive overflow of degeneration into the antero-lateral descending tract region and ground bundles was seen, the area of the ventral portion of the cord thus occupied by degeneration being very much more extensive than in the cervical cord. A few scattered degenerated fibres were seen in the white matter between this ventral area of degeneration and that of the crossed pyramidal and direct cerebellar tracts. In the lumbar region of the cord (see Fig. 4)

FIG. 4.

Transverse section of the lumbar region of the spinal cord in Case 2.

there was marked degeneration of only a part of the posterior columns. The septo-marginal descending tract was well preserved, as were the cornu-commissural zone and the outer part of the postero-external column bordering on the posterior horn and root. The whole of the periphery of the cord between the posterior root and posterior median septum, including the posterior root zone, was fairly preserved. There was marked degeneration of the crossed pyramidal tracts and the change was limited to their confines. A patchy and scattered degeneration existed in the direct pyramidal tracts and antero-lateral region at the periphery of the cord, with some scattered degenerated fibres in the ground bundles. Here and there a degenerate fibre was seen between the ventral area of degeneration and the lateral columns. In the sacral cord the septo-marginal descending tracts in the posterior columns were well preserved, while a limited narrow strip of marked degeneration existed on each side just external to them, somewhat patchy and of different extent and distribution on the two sides. A little scattered degeneration was also seen external to this more altered area. The cornu-commissural zone was intact on both sides. The crossed pyramidal tracts were degenerated but there was no evidence of degeneration in the direct pyramidal tracts or antero-lateral region of the cord. In addition to the degeneration of the various tracts of nerve fibres there were pronounced changes in the grey matter, consisting in destructive changes in the cells, diminution in the number of the fine nerve fibres which coursed through it, and increased vascularity. The degree of destruction of the nerve cells of the anterior horns varied at different levels. Some sections of the cervical cord showed that a large number of the cells had disappeared, others were markedly atrophied, while here and there small groups of apparently unaffected cells were seen. In other sections the groups of intact cells were much larger, while in some while there was a marked diminution in the number of cells of one anterior horn in the other the changes were much less pronounced. The same may be said of the thoracic region of the cord, where there was a great sparcity of cells and a great many of those present were atrophied. Similar

Digitized by Google

changes were seen in the lumbar cord but fewer cells were atrophied, while many of those present appeared to be swollen. The cells were plentiful in the sacral cord but many appeared to be somewhat swollen, while the pericellular space in some cases was so large as to suggest a certain amount of shrinking of the swollen cells. There was an increase in the number of vessels in the affected areas of white matter, especially the posterior columns; the majority of the vessels had greatly thickened walls with multiplication of nuclei, some appeared to be hyaline, and all were intensely engorged. Pronounced as were these vascular changes throughout the cord in no other part was there so great an increase in the number of capillaries met with as in the lumbar region, where there was a perfect meshwork of small thin-walled engorged vessels in addition to larger vessels with thickened walls. The neuroglia was thickened in the affected area but there was no infiltration of the tissues with round cells, nor were there any perivascular collections of these, and though the vessels were so engorged no hæmorrhages could be detected.

Remarks.—It would serve no useful purpose if we were to speculate as to the nature of the past illness which resulted in the patient's losing the sight of his right eye. A sufficiently long interval elapsed to justify our assuming that there was no direct connexion between that illness and the condition which resulted in his death. The earlier part of the clinical history of the last illness conformed to what we regard as more or less characteristic of ataxic paraplegia, while the subsequent development of anæmia and muscular flaccidity and abolition of the reflexes, together with the rapidly fatal issue, were in keeping with one class of cases of combined cord changes associated with anæmia in which the anæmia only becomes obvious late in the course of the illness. The changes met with in the spinal cord post mortem are such as are seen in ataxic paraplegia and in the cases of spinal cord changes associated with anæmia. It is obvious, therefore, that this case goes far to prove that there is a very close relationship between these two forms of affection of the spinal cord, if, indeed, they be not eventually proved to be identical. It is interesting to note that in contrast to the first case the changes in the sacral region of the cord are most pronounced in the crossed pyramidal tracts and are only slight in the posterior columns, the reverse of that which obtained in the other case.

CASE 3.—A married woman, aged fifty years, was admitted into the National Hospital for the Paralysed and Epileptic on Dec. 19th, 1894, under the care of Sir William Gowers, complaining of weakness in her arms and legs, numbness and tingling in her hands and feet, girdle sensation, and loss of control over the sphincters. Her father died from apoplexy at the age of sixty-three years; one brother had died from variola and another from rheumatism but otherwise the family history was good. She had been married thirty years and had had two sons and one daughter who had survived, while eight children had died in infancy, and she had had one miscarriage. The patient had not suffered from any previous illness, had always been temperate, and had lived in comfortable circumstances; but for six months she had nursed her husband, who died from phthisis five months before she came into hospital. She became ill after her husband's death, feeling great weakness in the lower limbs which caused her to fall about, and in a fortnight's time she was obliged to take to her bed and had not been up for more than a few hours since. At the commencement of her illness she noticed numbness and tingling in her hands and feet, and she had since suffered from girdle pains at the level of the umbilicus but had never had any cramps or lightning pains in the limbs. For three months she had been unconscious of passing her evacuations and both urine and fæces had been passed in her bed; the former did not dribble but passed in a stream; she was not, however, conscious of any desire to pass urine. There had never been any diplopia. On admission there was no loss of power noted in the lower extremities as she lay in bed, and the upper extremities, though relatively not so strong as the lower, presented no definite loss of power. She was unable to raise herself from the horizontal to the sitting posture and was unable to stand alone, and when supported she lifted her feet rather high and stamped them down in walking. There were no contractures, the knee-jerks were equal, there was no ankle clonus, the elbow-jerks were absent, and it was doubtful if any jerks could be elicited at the wrists. The inferior extremities felt cold and stiff, there were tingling and numbness in the fingers and feet, pain in the lumbar region of the spine and in the hypogastrium, with a girdle sensation just above the pubes. There was a loss of tactile sensibility over the right inferior extremity up to the level of the brim of the pelvis in front and to the fold of the buttock behind, with inability to recognise pin-pricks below the knee in front and up to the middle of the thigh behind. In the left leg there was slight blunting of sensibility for tactile impressions up to the middle of the thigh in front and to just below the fold of the buttock behind and there was blunting to pin-pricks over the same area. The plantar reflexes were equal and brisk, while the abdominal reflexes were not obtained. The fundi were normal, the pupils responded normally, there was no nystagmus or ocular paralysis, and the other cranial nerves were also intact. Ten days later the patient complained of bearing-down pain in the abdomen and back; there was retention of urine and incontinence of fæces, and from this time her urine had always to be drawn off by means of a catheter. She was unconscious of the passage of urine and occasionally of the passage of fæces also. A fortnight after this the knee-jerks became extremely feeble and in about two months from the time of her admission they were abolished. The lower limbs were drawn up, flexed at all the joints, and rigid, resisting attempts at passive movement. There were absolute loss of power in the lower extremities, with loss of muscular sense, inability to sit up in bed, and great weakness, unsteadiness, incoördination and loss of muscular sense in the upper extremities, while the intercostals and diaphragm acted fairly well. There was loss of sensibility for tactile and painful impressions up to the brim of the pelvis in front and up to the tenth dorsal spine behind, except the back of the left thigh where there was only blunting and over the lower third of this thigh in front where there was loss of sensibility for painful impressions but where tactile sensibility was only blunted. On the trunk tactile sensibility was blunted up to the level of the fourth rib on the right side and the third rib on the left side. The patient's replies were not to be relied on when the arms were tested, except that she always felt a pin-prick. As regards tactile impressions she sometimes said she could feel while at other times she said she could not. Her urine had always to be drawn off, there was complete loss of control over the sphincter ani, and she was unconscious of the act of defecation. Her general condition was very bad; there was marked general wasting, not limited to any parts specially, with marked tendency to trophic disturbance in the shape of a sacral bedsore and a small black patch on the right heel. So, too, two drops of hot water dropped on the chest gave rise to sores, which at first sloughed, but afterwards healed. The sacral bedsore also improved under treatment. About this time she developed general bronchitis. A week or two later the patient began to wander and to suffer from delusions at night; but during the day, though dull and slow, she remained fairly clear mentally. Her fundi were examined the day before she died and were found to be normal. The fatal termination of the case resulted on March 10th, 1895—i.e., about eight months after the commencement of her illness.

Necropsy.—At the post-mortem examination, performed by Dr. W. S. Colman fourteen hours after death, the body was found to be very thin, with a bedsore over the sacrum. The brain was found to be much wasted, with a large amount of compensatory fluid beneath the arachnoid, but the organ was otherwise natural to the unaided eye, as were the cerebellum and pons, but the medulla low down showed some degeneration in the posterior columns. The cranial bones and meninges were natural, as were those of the spinal cavity. The external appearance of the spinal cord was natural, but on section some discolouration was noticed in the posterior columns down to the lumbar enlargement, while none could be seen in the sacral region of the fresh cord. There was nothing else noteworthy beyond the fact that the liver was enlarged and tough, its capsule thick and opaque, and its lobules very distinct (no iodine reaction). The spleen was enlarged and soft and the kidneys were very tough, with a little thinning of the cortex.

Microscopical examination.—I subsequently made the following microscopical examination. The medulla oblongata only showed changes towards its caudal end, and these consisted in marked degeneration of the fibres of the funiculus gracilis and cuneatus on each side and similar degeneration of both direct pyramidal tracts, all of which changes were obvious in sections stained by Pal-Weigert method. Specimens prepared by Marchi's method showed

Digitized by Google

more recently degenerated fibres in the funiculus cuneatus than in the funiculus gracilis, and in both nearly all such fibres were seen in the deeper parts bordering on the grey matter, though some also were seen at the dorsal periphery of the funiculus cuneatus. Fibres in a recent state of degeneration were also seen throughout both direct cerebellar tracts, but most in the deeper parts of both tracts bordering on the formatio reticularis. This method further revealed recently degenerated fibres in large numbers in the restiform body on each side and a few scattered degenerated fibres in the pyramids, which fibres could be seen crossing at the decussation of these structures. Examination of the spinal cord showed that in the cervical region, as seen with a lens of low magnification, there appeared to be a complete absence of normal fibres in the postero-internal column, even the cornu-commissural zone sharing this fate. The postero-external column was also degenerated, though less markedly than the postero-internal, and a band of healthy fibres separated the grey matter from the altered part of the postero-external column. This zone of healthy fibres was most marked in the ventral part of the tract and existed only as a very thin band in the dorsal part of it. Fibres in a recent state of degeneration were conspicuous by their absence, very few being seen except in the zone between the grey matter and the ventral part of the more pronouncedly degenerated area of the postero-external column. There was marked degeneration in the lateral region of the cord, occupying chiefly the confines of the crossed pyramidal, direct cerebellar, and posterior part of the antero-lateral ascending tracts. In parts there was almost as complete a disappearance of nerve fibres as in the postero-internal columns, but on the whole the change was less pronounced than in these tracts. The lateral limiting layer was preserved. Recently degenerated fibres were scattered throughout the lateral columns, in some parts of which they were numerous while in others they were scarce. There were a considerable number in the ventral part of one crossed pyramidal tract and they were also numerous in the lateral limiting layer. The ventral part of the direct cerebellar tract and the dorsal part of the ascending antero-lateral tract were similarly occupied by a considerable number of such fibres in a recent state of degeneration. There was a moderate amount of degeneration in the direct pyramidal tracts and, as seen in the specimens prepared by the Pal-Weigert method, the change was most marked in the ventral part of these tracts, though slight throughout along the margin of the anterior median fissure. Ventrally the area of degeneration tended to encroach on the antero-lateral

FIG. 5.

Transverse section of the thoracic region of the spinal cord in Case 3.

descending tract region of the cord and two islets of degeneration were present in the course of this tract on one side, one opposite the anterior angle of the anterior horn and the other opposite a point midway between this and the lateral horn. A few fibres in a recent state of degeneration were scattered through the direct pyramidal tracts.

Sections from the thoracic cord (see Fig. 5) showed that the postero-internal columns were as markedly changed as in the cervical region, and that the degeneration of the postero-external columns was more pronounced than in the upper regions of the cord, being in great part as advanced as that seen in the postero-internal columns. The cornu-commissural zone was, however, more preserved than in the cervical cord and the band of healthy fibres separating the grey matter from the degenerated part of the postero-external column was more extensive. Fibres in a recent state of degeneration were present in both these zones of apparently healthy fibres, the number of these varying at different levels. The amount of degeneration of the lateral tracts of the cord was more extensive in area, as was that of the ventral portion of it, so that a smaller amount of apparently normal white matter separated the lateral degenerated area from that in the ventral portion of the cord. Less of the lateral limiting layer was preserved on one side than on the other, and recently-degenerated fibres were seen in these better-preserved parts. Such fibres in a recent state of degeneration were also present in the crossed pyramidal tracts and chiefly in one direct cerebellar tract, though they were present in the other also. The precise distribution of these fibres varied at different levels, so that in some sections they were much more scattered and irregularly distributed in the lateral columns than in others. The anterior columns were only affected in their ventral half as seen in specimens prepared by the Pal-Weigert method, with marked extension of the degeneration into the adjacent ground bundles and antero-lateral marginal tract to opposite the external limit of the anterior horn, but even in the healthy part there was evidently a sparseness of normal fibres in the region between the anterior and lateral columns of the cord, especially a short distance from the periphery. Exceedingly few recently-degenerated fibres were, however, seen in the changed and unchanged parts of the anterior columns. In the lumbar region of the cord

FIG. 6.

Transverse section of the lumbar region of the spinal cord in Case 3.

(see Fig. 6) the most pronounced degeneration of the posterior columns was in the middle third of the postero-internal tract, with the exception of that part of it occupied by the fibres of the septo-marginal tract which was preserved. The cornu-commissural zone and a band of fibres between the grey matter and the degenerated part of the postero-external columns were also preserved. Otherwise a scattered degeneration was present in the posterior columns. Recently-degenerated fibres were also scattered through these tracts, but were most marked in the better preserved parts, such as the cornu-commissural zone, the septo-marginal tract, and the band of fibres bordering on the grey matter. Next to no recently-degenerated fibres were seen in the most altered parts of

the posterior columns. The caudal end of the lumbar region was characterised by marked degeneration of the posterior two-thirds of the postero-internal column, the anterior third of the posterior columns, including the cornu-commissural zone, being intact. The septo-marginal tract was only fairly preserved, there being scattered degenerated fibres in it. The postero-external column was less degenerated than the postero-internal, and the zone of fibres bordering on the grey matter was preserved, as was also a very narrow peripheral zone at the dorsal end of both posterior columns. There was marked degeneration of Lissauer's tract, while the crossed pyramidal tracts were only slightly degenerated and the other tracts of the cord were practically intact. In the sacral region a little scattered patchy degeneration was to be seen in the posterior columns, especially in the dorsal part of the postero-external column, where there was a fairly well-defined patch of degeneration on one side. At the caudal end of the sacral cord, however, there was practically no degeneration except of Lissauer's tract, which was considerably degenerated, though to a less extent than in parts less caudally situated.

As in the two other cases so here there were changes in the grey matter, vessels, and interstitial tissue of a pronounced character. The anterior horn cells had largely disappeared in the cervical region, a few atrophied ones remaining in places, while other small groups of cells were fairly preserved, though even these stained badly as a rule. Similar changes were seen in the thoracic cord, where the cells were even more scarce. Few cells were preserved in the cephalic end of the lumbar cord, but towards the caudal end of this region of the cord it was chiefly the ventral part of the anterior horn that was poor in cells, and those remaining here were markedly atrophied. In contrast to other parts of the cord the anterior horns in the sacral region were rich in cells. In some sections, however, there was a sparseness of them, while others were obviously atrophied. Throughout the cord sections stained by Marchi's method showed the cells to be markedly granular and the majority stained black. Many of the fine fibres in the grey matter stained badly, while others were obviously degenerated. The vascular changes consisted in thickening of the vessel walls, some to such an extent as to almost occlude their lumina, marked engorgement of them, and a large increase in the number of capillaries in some parts. The grey matter of the sacral cord was crowded with engorged capillaries, while vessels with thickened walls were only seen here and there. In the lumbar cord the capillaries were fewer than in the sacral, while vessels with thickened walls were more plentiful. The latter form one of the chief features of the vascular changes in the thoracic and cervical regions of the cord, and such vessels were seen in the affected tracts of white matter as well as in the grey. Indeed, another feature of the thoracic, and more especially of the cervical, cord was the great increase in the number of vessels in the affected parts of the posterior columns. No hæmorrhages were to be seen either in the affected grey or white matter. There was much thickening of the neuroglia in the affected areas of the cord, and this change was most pronounced where the degeneration of the nerve elements was most intense—viz., the posterior columns, especially the postero-internal tracts.

Remarks.—This case is an admirable instance of the occurrence of the clinical features and morbid changes which characterise cases of spinal cord changes in anæmia in a patient in whom if anæmia was present it was not sufficient to attract attention and in whom neither during life nor after death were the signs by which we recognise pernicious anæmia detected. It is noteworthy, however, that although there was no obvious anæmia a condition of profound marasmus existed. Like the other two cases subjective sensory disturbances and inability to coördinate the movements of the inferior extremities were among the earliest manifestations of the disease. Spasticity was never a prominent feature during the time that the patient was under observation, sensory defects, muscular enfeeblement, and ataxy being the leading symptoms pointing to affection of the nervous system. But, as in the other cases, the final stages of the disease were characterised by abolition of the reflexes, flaccidity, and loss of control over the sphincters. As regards the degenerations in the spinal cord, it is noteworthy that their distribution in the lower lumbar and sacral regions of the cord was rather intermediate in type as compared with what was met with in the other two cases, but that it conformed more to the condition met with in the first case than to that met with in the second in that the changes were more pronounced in the posterior columns than in the lateral tracts in these regions of the cord.

General Remarks.

A comparison of the clinical histories of the foregoing three cases is alone sufficient to convince one that they belong to the same category of affections of the spinal cord, and any doubt which may have existed on this point could not reasonably be entertained after comparing the morbid changes met with and their distribution in the three cords. It is equally evident that the clinical manifestations and the nature and distribution of the morbid processes are such as have been described as typical of a group of cases in which symptoms indicating the existence of disease of the spinal cord are associated with profound anæmia. But the character of the nervous symptoms, their mode of onset, progress, and termination, harmonise fairly well with what is met with in ataxic paraplegia, the rate at which one event succeeds another and eventually terminates in death within one or two years from the commencement of the illness being alone contrary to what we have been in the habit of regarding as characteristic of this affection. This rapid progress to a fatal termination corresponds rather to what we would expect in some more or less chronic slowly progressive form of myelitis. The morbid changes met with on post-mortem examination, however, exclude this possibility, while they are quite in keeping with what we are in the habit of finding in cases which clinically present the features of ataxic paraplegia. While there is this general resemblance of the three cases to each other, and they collectively present features characteristic of a certain group of diseases which form a clinical and pathological entity, they individually serve to throw light on certain side issues with regard to the etiology and pathology of the disease of which they are examples. The first case is one in which the association of profound anæmia with the spinal cord changes is unquestionable, but in that the anæmia did not conform either clinically or post mortem to the rules which have been laid down for the diagnosis of the pernicious variety the case serves to emphasise the fact that such spinal cord changes may occur in profound anæmias not having all the characteristics of so-called pernicious anæmia. The second case furnishes an example of the fact that the symptoms of the spinal cord affection may precede any evidence of anæmia and that for a very considerable period of time, in this case about a year and ten months. Of the three cases perhaps this serves more than any of the others, at any rate clinically, to show how close is the association between the cases of combined sclerosis occurring in anæmia with those of so-called ataxic paraplegia or postero-lateral sclerosis. The third case makes it clear that cord changes indistinguishable from those which have been described in profound anæmia may occur without any obvious anæmia throughout the short clinical course of the affection. The patient was, however, markedly debilitated and in a condition of extreme marasmus and it is quite possible that had she lived longer anæmia might have been a late feature in this case as in the second here recorded.

That a close association exists between the changes in the spinal cord and profound anæmia in some cases is beyond question, but it appears equally certain that the cord changes cannot be attributed directly to the anæmia from an etiological point of view, as has been supposed to be the case by some writers. The fact that cases occur, like the third here recorded, in which anæmia, if present, has at any rate not been sufficiently prominent to attract attention argues strongly against the view that the spinal cord changes depend on the anæmia. So, too, instances have been recorded by Nonne,[6] Minnich,[7] Arning,[8] Teichmuller,[9] and Bödeker and Juliusberger[10] where, like the second case, the clinical manifestations of the spinal cord affection preceded any obvious signs of anæmia, which further argues against this view. Another consideration which is opposed to this hypothesis and to which sufficient weight has not been given is the fact that the number of cases of spinal cord changes of this kind is small compared with the large numbers of profound anæmias met with from

various causes, even if we excluded the cases of chlorosis in young girls. Even in these Nonne would expect cord changes to occur, for in concluding that all anæmias of a progressive character may lead to degenerations in the spinal cord he asks if it is not possible for them to exist in cases of chlorosis also. It has been suggested that phenomena such as the absence of knee-jerks sometimes met with in cases of chlorosis may indicate a minor degree of a similar change which in the graver forms of anæmia becomes of so pronounced a character. I, however, venture to contend that the two conditions are not strictly comparable. Prévost[11] showed experimentally that depriving the lumbar centres of blood by compression of the abdominal aorta abolishes the knee-jerks, and I have shown[12] that the same thing occurs in general anæmia produced by bleeding and in cases in which asphyxia is artificially induced. So that if the spinal centres to which the knee-jerks are related be deprived of blood or supplied only with blood containing an excess of carbonic acid the knee-jerks are abolished. While the excess of carbonic acid may have something to do with this result in the case of asphyxia, reasons are given elsewhere[13] for regarding the want of oxygen as the more potent factor in both cases. My contention, therefore, is that in cases of chlorosis in which the knee-jerks are abolished or in which temporary paraplegia occurs such phenomena ought to be attributed to this starving of the spinal centres of oxygen leading to a condition of functional inactivity rather than to the action of an agent so powerful as that which is responsible for the profound changes met with in the spinal cord in cases of combined sclerosis whether associated with anæmia or not. The experiments of von Voss[14] are important in this connexion, for though he succeeded in inducing pernicious anæmia in animals by artificial means and in keeping them alive for periods up to twenty-four weeks, he could find no changes in their spinal cords such as have been found in these cases of combined degeneration in man.

A further argument which might be advanced against the view that anæmia is the cause of the combined degenerations of the spinal cord that have been met with in its association is that profound degenerations of the kind have not been met with in the severe anæmia which occurs in leucocythæmia, lymphadenoma, malignant disease, and the like. Too much cannot be made of this, however, for it is possible that the association has been missed through ignorance of the possibility of such an occurrence, and it may be that systematic examination of such cases in future with this object in view may reveal that such an association is very much more common than we supposed. A striking and instructive instance of the need for caution in this connexion is supplied by a case recorded by Michell Clarke[15] in which symptoms of spinal cord lesions were masked by those due to profound anæmia. Further, Eisenlohr[16] and Müller[17] have each found lesions of the peripheral cranial nerves in lymphatic leukæmia, and changes in the medulla oblongata have been found respectively by Kast[18] and Alt.[19] Then, again, Müller[20] observed a case of leukæmia with slight sclerosis of the postero-internal and to some extent of the postero-external columns, increasing in degree from the lumbar to the cervical part of the spinal cord with increase and thickening of the neuroglia and falling out of nerve fibres. Patches of degeneration were also found in the anterior and lateral tracts. And Nonne[21] has recorded two cases of leukæmia in which there were no nervous symptoms during life, but in which he found patches of degeneration in the anterior, lateral, and posterior columns non-symmetrically distributed. There was in addition in one of the cases sclerosis of the postero-internal columns throughout the cervical cord and slight symmetrical sclerosis of the outer part of this tract and median part of the postero-external column in the cephalic end of the thoracic cord. In spite of cases of this kind which appear to support the views of those who regard anæmia as the cause of the spinal cord degenerations now under consideration the bulk of the evidence is opposed to this hypothesis. It appears to me to be more reasonable to suppose, as has been done by Lichtheim, Minnich, Taylor, and others, that the anæmia and spinal cord changes are the result of a common cause in the form of some toxic state of the blood. I do not, however, concur with Taylor, whose opinion is shared by Michell Clarke, in supposing that the degenerations may in part be the result of the hæmorrhages which take place in the spinal cord, and which are regarded as comparable to those which occur in the retina, brain, and other parts in pernicious anæmia. It may be that the presence of such hæmorrhages in the spinal cord is to be so accounted for; but in that they have also been found in cases of combined degenerations of the spinal cord in which anæmia was not a feature in the clinical history, the hæmorrhages may be the result of the action of a toxin on the walls of the spinal cord vessels whether the poison is or is not capable of inducing anæmia also. We are, of course, familiar with hæmorrhages of the kind in connexion with the action of various toxins on the central nervous system. That they form no essential part in the etiology and pathology of the spinal cord affection under consideration is proved by the fact that the most pronounced degeneration of the nerve elements may be met with in these cases throughout the spinal cord, without any hæmorrhages or their remains being detected. Further, in that such hæmorrhages have been commonly met with in the spinal cord in cases of severe anæmia without clinical manifestations of spinal cord symptoms, and without any change at all comparable to that of the combined degeneration type, it is reasonable to suppose that had they anything to do with the condition now under consideration they would be met with more frequently, in view of the large number of cases of severe anæmia which occur. Anæmia may play a part, and that a not unimportant one, in reducing the resistive power of the nerve elements so as to render them less able to withstand the baneful influence of some toxin, a property which anæmia would share with other debilitating influences and cachectic states. Thus it may come about that anæmia or other impoverished states of the system, themselves dependent on the action of some toxin, may in their turn render the nerve elements more susceptible to the action of the same or it may be some other poison.

In cases like the third, and one recorded by Rothmann, in which without obvious anæmia a condition of general malnutrition and marked cachexia was associated with the spinal cord affection, it is impossible to believe that the nervous system does not share in the general impoverishment, and whether the toxic agent had commenced its special action of destruction on the particular tracts affected in the combined sclerosis before or after the nervous system had commenced to share in the impoverished state of the body generally, the lowered state of nutrition of the nerve elements could not fail to facilitate the special action of the toxic agent on the particular tracts of the cord found degenerated, whether that degeneration is dependent on the action of the same poison which induced the general cachexia or whether some altogether different toxin is responsible for it.

The admission by most observers that the changes in the spinal cord are the result of the action of a toxin, though an important step in our knowledge of the etiology and pathology of these combined degenerations of the cord, leaves much to be further elicited. Thus Rothmann regards the affection of the white matter as endogenous in origin and the result of a primary affection of the grey matter. Teichmüller also regards the change in the grey matter as important and looks on both the tract affection and scattered areas of degeneration in the white matter as the result of small hæmorrhages. Pétion[22] similarly looks on the sclerosis as consequent on small hæmorrhages, while Nonne[23] attributes the changes in the white matter to patches of acute myelitis occurring in the earlier stages of the affection, and Bödeker and Juliusberger hold a similar view in that according to them the affection is to be regarded as a disseminated myelitis, which has a predilection for certain tracts of the spinal cord. The existence of so many different views on this question must, in part at any rate, be due to the opinions of writers being based on the particular conditions found in the cases which have come under their

individual observations, for a general survey of the whole subject, giving due weight to the changes found in all the recorded cases, does not, it appears to me, admit of such diversity of opinion. Any view which attributes the changes in the white columns of the cord to a primary affection of the grey matter appears to me to be erroneous in that in no small proportion of the total number of recorded cases the grey matter has been found intact, while in a large number of cases in which changes have been found in the grey matter they have been slight and insignificant compared to the degeneration of the white matter, so that the latter could not possibly depend on the former changes. Moreover, there is a wonderful symmetry in the affection of the white matter, while changes in the grey matter when present are irregularly distributed as a rule. A further argument against this view is to be found in the fact that the parts of the white matter which chiefly escape are largely those the fibres of which are of endogenous origin.

The view which supposes the degenerative changes in the various affected tracts of the cord to be due to small hæmorrhages is equally untenable, for in many cases there are no hæmorrhages present nor can the slightest traces of former hæmorrhages be detected. Even when hæmorrhages are present they are too few too small and too scattered to possibly account for degenerations affecting tracts symmetrically and in their entirety throughout so large a part of the spinal cord and producing so profound an alteration as to result in the complete degeneration of certain of them in parts of their course. Moreover, did larger hæmorrhages occur at certain points in the cord so as to interrupt the greater parts of the same tracts on both sides, we should find some evidence of ascending degenerations of certain tracts above such lesions with their escape, at any rate in part, below them and of descending degenerations of other tracts below such hæmorrhages with partial or complete escape of the same tracts above them. Not only have no such large hæmorrhages ever been met with, but the distribution of the degenerations in the cord quite precludes such a possibility. It is only necessary to remember that in most of these cases the degeneration both in the posterior and lateral columns is most pronounced in the cervical and upper thoracic cord and that it diminishes in degree and extent in both pairs of tracts as we pass towards the cephalic and caudal extremities respectively.

The hypothesis which, while not regarding the degenerations in the cord as secondary to hæmorrhages, nevertheless assumes that they are of vascular origin in the sense that the degeneration commences in the immediate vicinity of vessels with altered walls, owes its origin to the observations of Nonne and Minnich, who both found areas of degeneration surrounding such vessels with altered walls. But as von Voss has pointed out, and as I can fully confirm, such areas of degeneration are often seen in the neighbourhood of perfectly healthy vessels, while on the other hand vessels with markedly changed walls may be seen in parts of the cord free from degeneration, and, further, small areas of degeneration occur with no vessel of any kind in their immediate neighbourhood. Burr [24] rejects the vascular theory owing to the fact that he examined the spinal cords in seven cases of pernicious anæmia and in all but one found changes present although he scarcely ever found changes in the blood-vessels. That the topographical distribution of the degeneration of the white matter of the cord depends on the vascular distribution there can be little question. This will be obvious if it is borne in mind that the blood-supply of a given transverse area of the cord is derived from two sources, the anterior median arteries in the anterior median fissure and the peripheral arteries. The former supply the grey matter of the anterior horns and the white matter bordering on them and the neck of the posterior horn including Clarke's columns, while the latter supply the whole of the rest of the white matter of the cord. The distribution of the affection of the white matter of the cord in these cases of combined degeneration is precisely that of these peripheral vessels.

We have seen that cases occur in which there is affection of both regions of these different vascular supplies—viz., the grey as well as the white matter; but we have also seen that there are other cases in which the changes are limited to the area of supply of the peripheral vessels. Why there should be this escape of the area of supply of the anterior median arteries in some cases is not clear; but this much seems certain—viz., that the affection of regions supplied by the peripheral vessels does not depend on pachymeningitis in these cases, as has been supposed by Marie to account for certain forms of combined sclerosis. Difficult as these differences are of explanation they are no more curious than is the fact that in an admittedly infective disease like acute anterior poliomyelitis there should be affection of the area of supply of the anterior median artery alone, while that of the peripheral arteries escapes entirely. This belief that the morbid condition owes its topographical distribution to the vascular distribution must not be interpreted as meaning that I am of opinion that the degenerations of the spinal cord are vascular in the sense that they depend on changes in the vessel walls, whose impermeability leads to impoverishment of the nerve elements. That such thickening of vessels occurs and that when it occurs it cannot fail to affect the nutrition of the parts supplied by such vessels is admitted; but that this is the primary cause of the degeneration of the nerve elements is far from my belief, in that cases have been recorded in which with extensive degeneration of the nerve elements no changes in the vessel walls have been detected. I regard the changes in the vessel walls as rather depending on the same cause as the parenchymatous degeneration of the nerve elements, and that the only part played by the vessels in the initiation of the morbid changes in the nerve elements is that of bringing the toxic material to them.

We have lastly to consider the view of Nonne and of Bödeker and Juliusberger, who regard the degeneration as the result of disseminated myelitis. The objection which has been advanced against considering the degenerations as the result of hæmorrhages to the effect that parts of certain tracts should be affected above such lesions and should escape below, while others should be affected below and escape above, is equally applicable in the case of myelitis. Then, again, although we see all stages, including what appears to be the earliest of the changes in the spinal cord, we never meet with a round cell infiltration of the tissue so characteristic of changes of inflammatory origin. What, then, are we to regard as the mode of origin of the changes met with in the various nerve tracts of the spinal cord? The answer appears to me to be simple. We have already admitted that a toxin is responsible for the production of the spinal cord changes, and nothing appears more natural than that this toxic body (whatever may be its chemical nature) should by its action on the nerve elements result in a parenchymatous degeneration of them. Such a theory accords best with the changes found and with their distribution. The most reasonable explanation which can be offered as to why some parts of the cords are affected and others are not is that all parts of the central nervous system are not equally prone to be deleteriously affected by one and the same toxic agent, and that while certain parts are exceedingly easily damaged by one poison others have a peculiar power of resistance to the action of such a toxin, while it may be that these very parts are much less able to resist the action of some other toxin which may have little or no effect on the parts so susceptible to a poison having different properties.

Another question which deserves fuller consideration than I have already given it in this paper is how far we are justified in regarding all the cases of combined sclerosis of the spinal cord as belonging to the same category. That there are many totally distinct diseases in which tracts of different function are simultaneously affected, or in which the affection of tracts of a certain function is followed by similar affections of other tracts of entirely different functions, is obvious; but there also appear to me to be conditions in which the tracts are so affected, and which are at present regarded as distinct from each other, which should be regarded as identical. As coming within the former category I would instance the following. 1. Cases of tabes with affection of the crossed pyramidal tracts, those with degeneration of the direct cerebellar tracts alone or in conjunction with the crossed pyramidal tracts. 2. Cases of primary lateral sclerosis in which the posterior columns become secondarily affected or in which the direct pyramidal and direct cerebellar tracts are involved and the posterior columns remain normal. (The only recorded cases of the latter are open to question in that the posterior columns may have been affected in the upper unexamined part of the cord in one case and in that Goll's columns were intensely stained by carmine in the

[24] University Medical Magazine, April, 1895.

Digitized by Google

cervical region in the other case.) 3. Combined sclerosis of the posterior and lateral columns in general paralysis of the insane. 4. Friedreich's hereditary ataxy. In the second category I would include all those cases in which, with or without the presence of anæmia, degeneration occurs in tracts of different function in the spinal cord simultaneously or in quick succession and in which, irrespective of the duration of the clinical history or the precise order of occurrence of the phenomena dependent on affection of the tracts, there is found post mortem degeneration of the posterior columns, the crossed and direct pyramidal tracts, and the direct cerebellar tract. But it will be obvious that further subdivision of this great group will be necessary if we are to include in it conditions with so wide a difference in length of clinical history as the cases which we have been considering and those described by Gowers as ataxic paraplegia. Let us consider what justification there is for including in this group those acute cases in which, without anæmia, there occur symptoms attributable to affection of the spinal cord indistinguishable from the symptoms which occur in the cases associated with anæmia, the anæmia cases and those which have been described under the title of ataxic paraplegia. Sir William Gowers's description of the clinical features of the last condition leads me to conclude that its course is essentially chronic. While true of many cases, however, exceptions certainly occur to the rule, if, indeed, the rule is still to hold good now that with a wider experience of the condition we find that so many cases presenting the clinical and pathological pictures of ataxic paraplegia differ from it only in one or two minor details, including a shorter clinical course. If we allow that cases of ataxic paraplegia may run a subacute or even an acute course, then there seems little or nothing to separate this class of cases from the cases of combined cord changes which have been described in anæmia. How closely similar the conditions are is well exemplified by two cases recorded by Wagner [25] as instances of postero-lateral sclerosis in the sense that we would regard them as cases of ataxic paraplegia, but which, if a distinction is to be drawn between ataxic paraplegia and the cord changes which occur in anæmia, must unquestionably be relegated to the latter category. Oddly enough, however, Wagner does not appear to have been struck by the similarity of his cases to those which have been described in association with anæmia, although the morbid changes met with are indistinguishable from those found in the cases of anæmia. Further, one of his cases was markedly anæmic and in one the duration of the illness was only six months, while in the other it was two years. To admit that these cases are examples of ataxic paraplegia is to admit that this affection may run a subacute course, and such an admission also involves the necessity of our regarding all these cases of combined sclerosis as belonging to the same class—that originally known as ataxic paraplegia—irrespective of the length of the clinical history and as to whether anæmia was a feature in the case or not. Such a view would not be out of keeping with what we know of other diseases of the nervous system which owe their origin to the action of poisons, whether these are generated in the body or introduced into the system from without, for all such affections present marked variations as regards acuteness and chronicity and as regards the extent and intensity of the resulting morbid process. That such should be the case is only what is to be expected in that the rate of progress and the amount of damage done must of necessity depend largely on the virulence of the poison, its amount, and the resistive or other antagonistic properties possessed by the tissues on which it acts. If, as seems highly probable, therefore, the combined degenerations of the spinal cord owe their origin to the action of some toxic substance, there is no reason why such degenerations should not present all degrees of variation in their rate of progress and why the same poison should not generate the more chronic process of "ataxic paraplegia" and the more acute changes in precisely the same tracts of the spinal cord in the cases of anæmia and of cachectic conditions in which the resistive powers of the nerve elements must of necessity be lessened, whether these states of the general system were in existence before the poison commenced its special destructive action on the nerve elements or only became pronounced subsequently to this. From what has been said it will be seen that there is much which suggests a close relationship between ataxic paraplegia and the acuter forms of postero-lateral degeneration, but it would be premature to regard them as identical for there are some links in the chain of evidence which are still wanting.

HÆMATURIA AS A SYMPTOM: METHODS EMPLOYED IN MAKING A DIFFERENTIAL DIAGNOSIS;

WITH 19 CASES ILLUSTRATING POINTS OF INTEREST IN THE DIAGNOSIS OF RENAL AFFECTIONS CHARACTERISED BY THE PRESENCE OF BLOOD IN THE URINE.

BY DAVID NEWMAN, M.D. GLASG.,
SURGEON TO THE ROYAL INFIRMARY, GLASGOW.

THE appearance of blood in the urine during micturition is a symptom of a large number of different lesions and, as seen in surgical practice, may have its origin in any of the divisions of the urinary tract. Hæmaturia may be due to (*a*) lesions of the renal parenchyma or the pelvis; (*b*) disease of the ureters; (*c*) disease of the bladder; (*d*) disease of the prostate; (*e*) disease of the urethra; and (*f*) disease of the testicles. In this paper I shall endeavour in the first instance to discuss in a general way the characteristics of the urine in local lesions of the urinary tract in which hæmaturia is a prominent symptom and will describe in detail the exact methods which should be employed in making a differential diagnosis. Having done so, I shall classify the lesions of the urinary tract which are commonly associated with hæmorrhage and then describe in detail and illustrate fully by selected cases the etiology and symptomatology of renal hæmaturia. While in this communication only hæmaturia from lesions of the kidney will be illustrated by cases, I hope at a future time to publish a series of cases of disease of other portions of the tract in which the passage of blood in the urine was a prominent symptom and I shall then discuss the general question of treatment. I shall now refer to lesions of other portions of the urinary tract only in so far as it is necessary for differential diagnosis. We may classify the diseases of the kidney commonly associated with blood in the urine under the following heads:—(1) Traumatic lesions—(*a*) from injury and (*b*) from calculus; (2) Passive hyperæmia—(*a*) pressure on the renal veins, (*b*) torsion of the renal veins, and (*c*) reflex spasm of arterioles; (3) Inflammatory hyperæmia—(*a*) nephritis, acute and chronic, (*b*) tuberculous disease, and (*c*) cystic degeneration and hydatids; and (4) Tumours of the kidney. In the old nosological system of Vogel hæmaturia denotes a hæmorrhage from the kidney exclusively, but the name has been applied with different latitude of meaning by different writers. According to its etymological sense it should be restricted to cases in which blood is effused from the vessels in the kidney, ureters, or bladder and discharged along with urine, excluding from the definition urethral hæmorrhage in which the blood flows by drops or in a continuous stream from the orifice of the urethra and which is not properly a mictus cruentus. Every flow of blood from the urethra ought not to be considered a hæmaturia; a hæmorrhage having its starting-point in front of the muscle of Wilson ought to be distinguished from a true hæmaturia. The pathological conditions which are associated with the appearance of blood in the urine are very various and numerous, and while the great majority of these maladies are such that they naturally come under the cognisance of the surgeon many other cases of hæmaturia do not come under our consideration as they belong strictly to medical rather than to surgical practice. For example, hæmaturia may be an accompaniment of hæmophilia, septicæmia, typhus, enteric, or malarial fevers, small-pox, scurvy, or purpura; or it may be the direct consequence of poisonous agents, such as cantharides, alcohol, turpentine, phosphorus, and arsenic. Red urine is sometimes passed by patients who have taken sulphonal in large doses or for a long period. The Burgundy-red colouration is not due, however, to blood, but to the presence of abnormal pigments, urohæmatoporphyrin or its allies.

Eliminating such sources of hæmorrhage and considering

Digitized by Google

only those of a purely surgical nature, it may be said that the presence of blood in the urine indicates disease in some portion of the urinary tract; the red corpuscles may escape from the capillaries of the kidney and become mixed with the urine as it is secreted, or the urine may escape from the collecting tubes of the kidney in the normal state and afterwards become tinged with blood from the calyces, the ureters, or the bladder. How, then, are we to form a differential diagnosis of the source of the hæmorrhage? This may be done in several ways. First, by observing *(a)* the physical characters of the urine and of the blood-clot, *(b)* the admixture of other deposits with the blood, *(c)* the time at which the blood appears in the stream, *(d)* the frequency and duration of attacks, and *(e)* the effects of movements and exercise or of complete rest in the course of an attack. Secondly, by collecting the urine separately from the two ureters or by observing blood escaping from the orifice of a ureter. Thirdly, by estimating the quantity of hæmoglobin and comparing it with the amount of albumin in the urine. Fourthly, by carefully considering all the other accompanying objective and subjective phenomena. In acute disease the diagnosis between hæmaturia of renal and vesical origin is usually easy, but it is frequently otherwise in chronic affections. In the former the objective and subjective phenomena are so pronounced as clearly to indicate the organ which is affected; in the latter the most careful observation of minute details is often necessary in order to determine the seat of the lesion, and in not a few instances examinations conducted by different observers may lead to disagreement as to whether the secreting, the conducting, or the collecting portions of the urinary system are at fault. I shall endeavour to sketch and illustrate by cases under the divisions just enumerated a systematic inquiry respecting the signs and symptoms accompanying hæmaturia in so far as they may lead us to a differential diagnosis of the source of the blood.

1. (a) Physical Examination of the Urine and the Circumstances connected with the Presence of Blood in the Evacuation.

The following questions must be inquired into and answered: What is the colour of the blood? Is it intimately mixed with the urine and is the whole stream equally colourised? Is the quantity of blood augmented by exercise or diminished by rest? Have clots been seen, and what is their form? Are there tube-casts or blood-casts to be discovered, or are there other deposits found in the urine? Are the attacks frequently repeated and of short duration, or are they protracted? These are some of the most important points to inquire into, and presently I shall discuss them in detail. The colour imparted to the urine by the addition of blood varies greatly in intensity and shade—from a pale rose colour to a bright red like red-currant syrup mixed in water, to a dark red, to a colour simulating porter, or to a brown colouration not unlike coffee. As a general rule, however, it may be stated that the nearer the source of hæmorrhage is to the external orifice of the urethra the less is the blood altered in appearance. Sometimes, however, as in cases of tumour of the kidney, the quantity of blood derived from an organ may be so large in amount and may be expelled so rapidly after it has escaped from the vessels that little change may be observed in its colour. Again, as will be illustrated presently, in some cases of rupture of the kidney from direct violence, the urine may be of a bright red colour, the blood having undergone very little change, but if there is no history or symptoms pointing to tumour of the kidney or to rupture of the organ from injury the above statement may be accepted as correct. On the other hand, when the hæmaturia is of vesical origin the first quantity of urine passed may present a normal appearance, especially if the patient has been for some time at rest in a recumbent posture and the urine is passed while the patient is in bed, but in such circumstances as the bladder empties itself the urine gradually becomes more and more tinged, till finally the last drops evacuated may be almost pure blood. This is to be especially noted in cases of tumour of the bladder and of vesical calculus, also in passive hyperæmia of the bladder. In passive hyperæmia probably the engorgement of the vesical veins is greatly augmented by the process of muscular contraction, the efflux trunks being compressed by the muscular trabeculæ through which they pass on their way to join the plexus of veins on the serous surface of the bladder. When the bladder is moderately full the veins are distended and gorged with blood, but when an expulsive effort is added to the already considerable tension the weak capillary walls give way and there may be considerable oozing of blood from the mucous surface without the appearance of any gross lesion when the bladder is examined with the cystoscope. As a general rule, in hæmorrhage from the bladder the urine is mixed with a considerable quantity of mucus and is of a bright florid colour; but if long pent up in the viscus it may assume a dark colour dependent upon the reaction of the urine, which in such cases is usually alkaline. When due to vesical calculus the hæmorrhage is increased by exertion and in cases of tumour of the bladder the bleeding is always worse after an attempt has been made to examine the bladder by instruments. When the blood is from the kidneys or the ureters it is generally intimately mixed with the urine, to which it imparts a dark smoky colour, unless when, as in Cases 7 and 12, the blood issues in considerable quantity from the pelvis of the kidney and flows rapidly along the ureter, distends the bladder, and escapes without undergoing much change. While it is true that usually blood of renal origin is freely mixed with the excretion which presents a smoky or coffee colour, too much importance must not be attached to these appearances, as they do not depend so much upon the source of the blood as upon the reaction of the urine itself—for example, in some cases of enlarged prostate and chronic vesical catarrh.

In cases where there is considerable residual urine freshly oozed blood may rapidly become smoky, and while at one time the urine may be clear and of a bright colour, while the corpuscles may separate rapidly as a deposit, on other occasions the colouring matter may be rapidly dissolved and the urine may present a distinctly smoky appearance. R. von Jaksch states that "when blood-cells are intimately mixed with the urine in such a way that though they present a large quantity of deeply tinged fluid they do *not* form a sediment after many hours' standing it may be inferred that the hæmorrhage took place in the substance of the kidney or in the renal pelvis or ureters. If under these circumstances they are seen with the microscope to be profoundly altered having lost their colouring matter and presenting the appearance of pale yellow rings, the further conclusion results that the blood has been effused from the kidney itself and the symptom points to acute nephritis or to a fresh exacerbation in the course of chronic nephritis." To this statement I cannot assent. In many cases I have seen on careful observation the urine of individual patients vary greatly from day to day, on some occasions presenting the characteristics described by Jaksch and at other times an altogether different appearance, while the hæmorrhage was proved ultimately not to be of renal origin.

Blood having escaped from the vessels its fibrous constituents may coagulate into firm clots which during their formation may entangle some of the histological elements of the structures in which they lie or by their firm appearance, form, or bulk may indicate the source of the hæmorrhage. Clots are seldom noticed in the urine unless in cases of abundant hæmorrhage; they may be few in number or numerous; generally they are soft in consistence, and when small in size they are easily dissolved in the urine and consequently, if not looked for immediately after micturition, they may be lost. The form of the clot may be ovoid, or may be long and worm-shaped, or may resemble in appearance a well-gorged leech. As to colour they are generally dark red, but may vary considerably, sometimes being black, bright red, or they may become partly or wholly discoloured—spotted red in a greyish background or entirely grey. When the clot is large, the hæmorrhage is usually, but not invariably, from the bladder; the clots may be so huge that they cannot pass along the urethra without being broken up either by the repeated contraction of the bladder or by means of instruments. These clots are generally very irregular in form and size; they may be so large as to be described by the patient as like masses of liver, but here again a conclusion must not be drawn from the size and appearance of the clot. It is generally said, and probably truly said, that these large masses of blood-clot are due to a vesical lesion, but many cases have been recorded, and some examples will be given presently, where large clots have been formed in the bladder and evacuated where the hæmorrhage has been clearly due to a renal lesion. The coagulum may make a complete cast of the pelvis or of the calyces. Three years ago, in a case of very acute parenchymatous nephritis, I had sent to me a clot of blood which was almost a complete cast

Digitized by Google

of the pelvis and a portion of the ureter of one kidney; and I remember many years ago in an exactly similar case finding at a post-mortem inspection both pelves occupied by blood-clot which extended down to, and protruded from, the orifices of the ureters into the bladder. Rounded clots corresponding to the diameter of the ureter may escape, or leech-like ovoid casts may be taken of the first part of the urethra, or long bougie-like coagula from its anterior part. While the presence of considerable clots is usually, though not always, conclusively against the idea of the hæmorrhage being from the secreting substance of the kidney the absence of clots visible to the eye proves nothing. If the passage of a long worm-shaped blood-clot is preceded by a temporary cessation of the hæmaturia and its escape followed by a recurrence of the bleeding this proves almost to demonstration that the clot has been plugging one ureter, and if in addition the clot is of such a size as to support the idea of being a mould of the ureter the evidence is conclusive as to the source of the hæmorrhage. The hæmorrhage has been from the kidney and blood has coagulated in the ureter and has completely plugged it, the coagulum has then become shrunken, while at the same time an accumulation of urine has taken place in the pelvis and caused dilatation of the ureter until a point has been reached where the onward pressure from above is so great that the clot has been forced out into the bladder along with an accumulation of blood-stained urine. I observed this lately in a case (Case 1) where palpation of the left kidney always brought on hæmaturia, but when the patient was left at rest the blood disappeared. The microscopic appearance of these clots varies according to their age and the changes they have undergone since coagulation has occurred. If the clot is freshly formed the blood corpuscles present practically a normal appearance and are seen to be well coloured and embedded in an amorphous or slightly granular matrix of fibrin; but if the clot is old, and especially if it is small in size, the hæmoglobin will be seen to have dissolved out and the red blood corpuscles to be represented only by little colourless rings from three to five micro-millimetres in diameter. These fragments of discoloured coagulated blood have sometimes been mistaken by microscopists for portions of tumours. I have had frequently sent for examination fragments of bleached blood-clot in the belief that they were portions of malignant tumours, especially sarcomata. The size of the cells, however, and the absence of nuclei, as well as the behaviour of sections when acted upon by staining agents, clear up the diagnosis. In several cases, the details of one of which will be described presently (Case 10), on examination with the cystoscope one ureter was found to be blocked by a coagulum which protruded from the orifice of the ureter and hung into the bladder, not unlike a small worm hanging from the end of a fishing hook. It was of a dark reddish grey colour and firm consistence, being evidently some days old. It was so firm that the examination of the bladder and the movements of the cystoscope disturbed it and its dislodgment was immediately followed by a copious flow of blood from the previously obstructed ureter. In renal hæmaturia minute coagula, casts of the uriniferous tubules, may be discovered in the urinary sediment by the microscope and may give evidence by their form and shape whence they are derived. In this form of hæmaturia the number of blood corpuscles is no criterion of the quantity of albumin in the urine, whereas in hæmorrhage from the conducting or collecting portions of the urinary tract, provided there is no pus in the urine, the number of red corpuscles or the amount of hæmoglobin may be accepted as the measure of the quantity of albumin contained in the excretion.

(*b*) *The Admixture of other Deposits with the Blood.*

In many cases of hæmaturia the only abnormal constituent in the urine is blood, while in other cases it is mixed with pus, mucus, tuberculous material, portions of tumours, or micro-organisms, the detection of which throws considerable light on the etiology of the malady. The mixture of the blood with deposits of another kind requires only to be mentioned here, as space will not permit me to enter into a detailed descripton of the various deposits which may be found. The three most common, however, I may mention—namely pus, mucus, and tuberculous debris. If the urine is placed in a conical glass and allowed to stand for a few hours, and the glass is then held up to the light, if pus is present in any great amount the deposits will be found in distinct layers like geological strata; the bottom of the glass is occupied by a yellowish deposit which may be more or less blood-stained pus, or, in some cases of renal pyuria, the pus may carry down almost all the blood corpuscles so as to leave an almost quite clear supernatant fluid. When mucus is present, on the other hand, not uncommonly the blood corpuscles may be thrown down first, forming a layer at the bottom of the vessel, and following upon this may be seen a layer of glairy gelatinous material which may have a reddish tint or may contain a multitude of minute bloody streaks which intersect it and penetrate into all parts of this gelatinous layer. In such cases the hæmorrhage is usually due to some lesion in the bladder and the presence of such an amount of mucus is generally indicative of a more or less acute vesical catarrh. The tuberculous deposit can only be distinguished by microscopic examination, by the cultivation of tuberculous bacilli, or by inoculation experiments. Beyond demonstrating the presence of blood-casts of the uriniferous tubules the microscope may reveal the existence of other elements of consequence in the deposit. For example, the character of the epithelium as derived from the renal parenchyma, from the pelvis, the ureter, or the bladder may greatly assist one in diagnosis; or, on the other hand, should the urine contain small fragments of tumours, parasites, or bacteria, the hæmorrhage may be explained.

(*c*) *The Time at which the Blood appears in the Stream.*

In order to ascertain the precise moment at which the blood appears in the stream it is necessary for the surgeon to see the patient urinate and to observe whether the colouration is equal during the whole continuance of micturition or is more abundant at the beginning or at the end of the act. The appearance of blood at the beginning of micturition, the remainder of the flow being clear, may be an indication of two distinct conditions: the lesion is either in the prostate close to the neck of the bladder or a malady or injury is present in the urethra. In some lesions of the prostate the blood may pass into the urethra and accumulate there; so also in lesions of the first portion of the urethra the blood may flow backwards into the bladder and mix with its contents. When the blood originates in the urethra and accumulates there, or when it escapes from the prostate and flows into the urethra, the hæmaturia is limited to the beginning of micturition, but if the quantity of blood is great and flows backward into the bladder and mixes with its contents then the whole of the urine becomes more or less coloured. Again, in a lesion at the neck of the bladder giving rise to hæmorrhage the hæmaturia is not limited to the beginning of micturition but blood is also observed to escape at the end of the act. This is easily explained; between the acts of urination the blood accumulates in the urethra or close to its internal orifice and is expelled with the first few drops of urine only, that following being clear, but again before complete contraction of the bladder occurs a fresh hæmorrhage is induced which shows itself in the urine last ejected. When the hæmorrhage is due to injury or disease of the urethra the nature of the lesion is generally clearly indicated by the circumstance that the blood is observed to escape quite independently of micturition; sometimes, indeed, blood is seen to flow from the meatus spontaneously. In cases of tumour of the bladder and also in vesical calculus the hæmorrhage is most profuse at the end of micturition.

(*d*) *The Frequency and Duration of the Attacks.*

While nothing absolutely definite can be ascertained by a close observation and study of the frequency and duration of the hæmaturiæ still considerable help may be got in this way to aid in a diagnosis. For example, in many cases of renal hæmaturia the blood may suddenly appear and just as suddenly disappear soon to be followed by a profuse recurrence; such sudden transformations are in some cases accompanied by the expulsion of long worm-shaped clots, and in such instances we may reasonably conclude that the sudden clearing of the urine has been due to the ureter being obstructed. The blood has coagulated within its lumen and when the clot becomes displaced a fresh and often apparently very profuse escape of blood is observed. The same sudden appearance and disappearance of blood has been observed in cases of moveable kidney with torsion of the renal veins (see Cases 11 and 12); also in cases of renal calculus (see Cases 9 and 10). When hæmaturia comes on without being evidently provoked we may generally surmise that the lesion

Digitized by Google

giving rise to it is a serious one although we may not be able to judge its site. In cases of tumour of the bladder the presence of blood is generally very persistent, without intervals, and of long duration, so that the patient may become very anæmic from loss of blood. Again, on the other hand, we meet with cases where hæmaturia more or less profuse has recurred at frequent intervals, but the duration of the attacks has been short and the intervals, between them marked by complete absence of any blood in the urine. Sometimes there may be periods of relief extending over several weeks or even months and usually any fresh recurrence of bleeding can be explained by excessive exercise or unwonted freedom of movement on the part of the patient. If these conditions are associated with the absence of vesical symptoms the strong presumption is in favour of the hæmorrhage being renal in origin and against the hypothesis that the blood is flowing from an ulcerated surface; the total duration of the symptoms is also an important guide to the benign or malignant nature of the malady giving rise to it. The long presence of a stone in the renal pelvis may, after causing occasional hæmaturia for years, be followed by the formation of a carcinoma. I published a case of this kind[1] in which there were symptoms of renal calculus for ten years, pain in and hæmaturia from the left kidney, albumin, and tube-casts from the right kidney. Within six months of death symptoms developed pointing to malignant disease, from which the patient died, and post mortem the left kidney was found to contain six oxalate of lime calculi, the pelvis and calyces were much dilated and the upper half of the kidney was occupied by an epithelioma (see Case 19).

(e) The Effects of Movement or Exercise or of Complete Rest in the Course of an Attack.

When complete rest is taken hæmaturia due to the presence of stone in the renal pelvis, in the bladder, or in the prostate is generally more or less relieved; so also in hæmorrhage observed in cases of movable kidney, or in passive hyperæmia of the kidney resulting from pressure on the renal veins. In such cases it is repeatedly observed that the blood is most abundant in the urine at night when the patient has been taking active exercise during the preceding day, while at the same time the pain in the renal region or irritability of the bladder is increased. It must, however, be also borne in mind, in exceptional instances, that in hæmaturia from an abraded surface, as in carcinomatous or tuberculous ulceration, or in senile prostate, the bleeding occasionally may not be increased by exercise, but as a rule if the hæmaturia persists in spite of prolonged rest in bed, and especially when the bleeding is more abundant during the night than at other times, carcinomatous, sarcomatous, or tuberculous ulceration is to be looked for.

2.—By Collecting the Urine Separately from the Two Ureters or by observing Blood escaping from the Orifice of a Ureter.

Various procedures have been employed to ascertain whether the blood originates in the bladder or flows into it from one of the kidneys and methods have also been devised to ascertain the nature of a vesical lesion. Examination of the bladder by means of the sound, the catheter, or with the finger have been at different times suggested and carried out in practice. When one reads Sir Henry Thompson's[2] description of how exploration of the bladder with the finger should be carried out the marvel is that the injury done to the patient was not appalling. He introduced the *left forefinger into the rectum* as a guide to the incision of the bladder, and when the incision was completed the same finger (*the left index*) presumably without being cleaned was used in exploring the bladder. Sir Henry Thompson[3] went further than this and proposed that portions of a growth might be removed from the main mass by means of a lithotrite and submitted for microscopic examination, surely overlooking the fact that pieces of a growth removed by a crushing instrument must have lost their histological characteristics and hence been rendered valueless for diagnostic purposes. Again, Kuster has employed a curette and Chismore used a calculus aspirator for diagnostic purposes. The use of such imperfect methods is now to be condemned seeing that we have at our disposal the electric cystoscope and ureter catheters, but in order to employ these instruments the surgeon must educate himself in their use, just as in the use of any other instruments of precision. The cystoscope may be used both in men and women and when properly employed the examination subjects the patient to very little risk—less, indeed, than the use of a sound. The sound is too frequently employed in cases of hæmaturia. It is only when the bleeding is the result of a vesical calculus or an enlarged prostate or an hypertrophy of the bladder that any reliable information can be gained by the employment of the sound, and when the hæmaturia is due to other lesions much harm may be done by the rough manipulation necessary to examine the bladder with that instrument. The educated use of the cystoscope being more gentle is less dangerous and it is more valuable, but it should always be used with strictly aseptic precautions. It must be remembered that where the bladder or other portion of the urinary tract is the seat of disease the risk of septic contamination is much greater than when these parts are normal, and when septic contamination does occur the gravity of the condition is proportionately greater. In all cases not only should the cystoscope itself be thoroughly sterilised, but the meatus and surrounding parts should also be carefully washed and rendered as free from contaminating particles as possible, and after examination has been made the bladder should be carefully washed out with a fresh supply of suitable antiseptic solution. Cases undoubtedly have been recorded where, especially in tuberculosis of the kidneys and bladder, dangerous pyelitis and cystitis have followed the use of instruments, but I feel convinced that such evil consequences could not have resulted if the precautions I have just indicated had been carefully attended to. I first suggested the employment of the electric light for examination of the human bladder in 1883 by introducing an electric endoscope into the female bladder. At that time the instrument was simple and for the female served its purpose well, but since then many improvements have been made, so that now for many years the male bladder has been open to inspection by means of Leiter's instrument. By making careful examination with the cystoscope it is usually easy to ascertain whether or not the blood is from the bladder, but in a few instances it is not safe to conclude from the fact of no lesion being observed in the bladder that the hæmaturia is therefore either renal or ureteral in its origin. When, however, the blood is seen by the cystoscope flowing from the orifice of a ureter, or more rarely from both ureters, the observation is of the highest importance as indicating the source from which the blood comes. The following case illustrates this.

CASE 1. *Hæmaturia; pain in the lumbar region and physical signs of left moveable kidney; torsion of the renal vein and the ureter; ragged orifice of left ureter; blood from left kidney only.*—The patient, a woman, was sent to me by Dr. Dunsmuir of Renfrew and in a letter he gave the following history: "She came under my observation on Feb. 17th last, when she complained of frequent micturition, blood in the urine, pain in the lumbar region, and something which she could not well describe in the left renal region. About twenty years ago, while in the act of lifting some heavy wet clothes out of the boiler in the washing-house, she felt as if something had broken in her abdomen and ever after had an uncomfortable looseness which she partly remedied by sewing a pad to her stays. About eight years ago acute pain supervened in the lumbar region and up to the present has been constantly there; it varies with position, being aggravated in the erect posture and minimised slightly by inclining forward. About seven weeks ago frequent micturition came on, and a few weeks later she took to bed and on passing urine her attention was arrested by its fearfully foul smell. On examining it she observed it to be perfectly black and was for the first time alarmed about her health. Since that time the urine has never been free from blood, but varies with her movements: smoky with deposit of mucus and blood-cells after a period of absolute rest, inky black after the jolting in a cab, and claret-coloured after each bimanual examination of the left kidney. Only one clot has been detected, which was of the length and breadth of the little finger-nail and one-eighth of an inch thick with a little tail attached. The abdominal wall is very lax, allowing a fairly easy bimanual examination, which elicited a tumour partly in the left hypochondrium, partly in the epigastric and umbilical regions of a firm consistence and kidney shaped." I examined the patient and found the left kidney mobile and considerably enlarged, and on examination of the urine the

Digitized by Google

deposit presented peculiarities which were difficult to explain, a red deposit was rapidly thrown down, and on microscopic examination it presented the appearance of shreds of fibrous tissue with minute fatty globules entangled in it; along with this numerous blood corpuscles were seen. The deposit was so different from anything that I had previously seen that I submitted it to others for examination, and the consensus of opinion was that these shreds were probably the débris from a renal or vesical tumour. Examination of the bladder with the cystoscope showed it to be practically normal, the only morbid condition was the appearance of the orifice of the left ureter, which was ragged and elevated and presented very much the appearance of the crater of a volcano. While observing the appearance of the ureter blood-stained material was seen to escape from it; this examination led me to suspect the presence of a tumour in the kidney, but the history of the case as given by Dr. Dunsmuir rather favoured moveable kidney leading to torsion of the renal vessels. With the assistance of Dr. D. McK. Dewar I exposed the kidney and found it to be healthy but very free and moveable; a large portion of the adipose capsule was removed and the kidney sutured to the parietes. Since the operation there has been no hæmaturia. During one of the attacks of hæmaturia, while the patient was in the "home," the blood suddenly disappeared and recurred five hours after, apparently more profusely than before. The clearing up of the urine was coincident with increase in the pain and swelling in the renal region and the reappearance of blood gave relief to the pain and swelling and a cast of the ureter was found in the urine.

(To be continued.)

THE PATHOLOGY OF NEUROPATHIC KERATITIS.

BY PERCY FLEMMING, F.R.C.S. ENG.,
ASSISTANT OPHTHALMIC SURGEON TO THE UNIVERSITY COLLEGE HOSPITAL.

THE occurrence of corneal lesions in association with affections of the trigeminal nerve is well known, but much difference of opinion exists regarding the exact nature of the relationship between the two lesions. The various hypotheses suggested fall into two main groups. In the one the keratitis is regarded as a direct example of perverted trophic action of the nervous system, whereas in the other such a supposed action of the nervous system is regarded as needless and the various effects are thought to be mainly due to the anæsthesia. This insensitive condition of the cornea may act in various ways. Thus foreign bodies may lodge on the cornea and, not being felt, may remain and cause irritation and ulceration. The stimulus to the reflex action of the orbicularis (blinking) being wanting the cornea will not be properly moistened, and this condition may also in part be due to arrest of activity of the lacrymal gland. Again, owing to the sensory paralysis slight injuries (with perhaps microbic invasion from the lacrymal sac or conjunctiva) may give rise to excessive vaso-motor reaction and in this way become more extensive and the reparative processes fail to take place.

During the last year several cases of "neuropathic keratitis" have been under my care at University College Hospital, and as each has some points of special interest I propose to briefly record them and at the same time to review previously recorded clinical cases and post-mortem examinations and also the experimental investigations, with the object of ascertaining how far such evidence favours one or other of the previously mentioned hypotheses.

Now, in the first place, constant exposure of the eye with consequent liability to injury and dryness does not at all necessarily lead to keratitis. Everyone is familiar with cases of old-standing Bell's paralysis in which the cornea has been exposed for years without any damage resulting. And it is quite exceptional to meet with a case of Graves's disease with an inflammation of the exposed cornea. Again, I have notes of a case of a patient who had a severe burn when a child, involving the forehead and eyelid, which prevented effectual closure of the lids, and yet after ten years there had not been the slightest sign of ulceration. Frequently associated with the fifth nerve lesion is a paralysis of other cranial nerves (oculo-motor, &c.), and the presence of ptosis, with consequent protection, does not prevent—though it may modify—the occurrence of typical neuropathic keratitis. And in one of my cases (Case 4) the keratitis developed subsequently to the involvement of the third nerve. Mendel and Hirschberg record a case in a child in which "neuroparalytic keratitis" existed in each eye, associated on the one side with facial paralysis and a sensitive cornea, and on the other with trigeminal paralysis giving rise to an anæsthetic cornea, but with no facial paralysis, and therefore no undue exposure.

In another group of cases the cornea may be completely anæsthetic for a long time and yet no keratitis be set up. The following is a case in point.

CASE 1.—A man, aged fifty years, came to the hospital with acute facial herpes, the patches being situated at the left angle of the mouth, the left lower eyelid and adjacent side of nose, and a fourth large patch on the right ala of the nose and lower lid of same side. Both corneæ were insensitive and no corneal reflex could be obtained, but both were quite sound. It was impossible to bandage both eyes, and as the herpes quickly subsided the man soon returned to work; and although the cornea remained insensitive for several weeks no ulceration or inflammation occurred.

Harlan[1] records a case where the insensitive cornea remained sound "for years" and Gowers mentions a similar one which had been under his observation seven years. And in another of my cases to be given in detail later, the cornea was anæsthetic for some time without being inflamed. W. J. Collins[2] has recorded a case where an anæsthetic cornea became cloudy "after eight months' anæsthesia with perfect pellucidity." Further, complete removal of the Gasserian ganglion in man, with consequent anæsthesia of cornea, is not necessarily followed by keratitis.

In a third group of cases, typical neuropathic keratitis exists with a normally sensitive cornea. Mendel and Hirschberg's case (previously quoted) is a case in point. Genkin reports another in which "trophic keratitis" existed with a normally sensitive cornea. Herpetic eruptions are generally regarded as trophic lesions. Two varieties of herpes of the cornea are met with—the one complicating acute febrile herpes and characterised by small vesicles on the cornea with much irritation which quickly subsides when the vesicles burst; the other occurring with herpes zoster ophthalmicus, differing from the former by the tendency to persistence of the irritation and to implication of the deeper layers of the cornea. The following case is an example of the former variety.

CASE 2.—A woman, aged thirty years, came to the hospital on Sept. 15th with much photophobia. On both upper and lower lids of the right eye were some drying up herpetic vesicles. The lids were separated with great difficulty and then a small superficial ulcer of the cornea was observed. Three weeks later the photophobia was still marked and the ulceration had spread. Ultimately the irritation subsided and the ulcers healed. In this case there was clearly no anæsthesia of the cornea.

In considering this group of cases it must be noted that Mr. Tweedy has for long taught and described that corneal ulcers, having the same clinical characters as those which occur in connexion with grave lesions of the fifth nerve, are frequently found with a normally sensitive cornea; and he thinks that their essential neuropathic nature is shown by the ready way they respond to efficient protective treatment, by the slight vascular reaction accompanying them, and by the frequency of a history of preceding neuralgia.

Lastly, in reference to the hypothesis that an insensitive cornea is less resistant to traumatism, it must be noted that operations on insensitive corneæ—insensitive, that is, from paralysis of the fifth nerve—may do quite well; and Panas[3] records an example of this where the operation was necessitated by a preceding attack of "neuroparalytic keratitis."

It seems fair to conclude from the consideration of these and similar cases that mere anæsthesia of cornea with consequent dryness and impaired vaso-motor reaction cannot be regarded as the essential factor in the production of the keratitis, though there can be no doubt that anæsthesia and also want of protection do modify the course of the

Digitized by Google

inflammation. And this conclusion is further strengthened by the fact (to be more fully emphasised later) that the keratitis is frequently preceded by iritis.

The evidence respecting the remaining hypothesis—namely, that the keratitis is the direct outcome of some perverted trophic nervous action—must be next considered. And in the first place there is a good deal of evidence of the existence of such trophic action of the nervous system in parts of the body other than the eye. The acute bedsores in some spinal cases, the perforating ulcer and joint affections in tabes dorsalis, the atrophy of the phalanges and joint lesions in syringomyelia, and the atrophy of skin and bone which may follow injuries of nerves are all cases in point. The last group of cases mentioned has an important bearing on the subject immediately under consideration, for Gowers states that atrophy of skin and bone in the finger-ends after a lesion of the nerve of the arm may proceed in spite of the existence and persistence of normal sensibility. So that the retention of normal sensation in a part does not in the least militate against the view that perverted trophic action is going on at the same time. Further, there is a good deal of evidence that the changes occurring in the condition known as facial hemiatrophy depend on lesions of the fifth nerve, and interstitial neuritis of this nerve has been found post mortem. And it is important to note that not only has typical neuropathic keratitis been observed in these cases but also patches of choroiditis with vitreous and lenticular opacities, these latter being probably secondary to changes in the uvea.[4] And, lastly, in association with severe cases of trigeminal neuralgia, trophic lesions such as a falling off of the hair and eyebrows or a whitening of them have been observed.[5]

Thus though it may be impossible to prove clinically that neuropathic keratitis is due to a trophic lesion yet such an explanation seems most probable. The further question then arises—viz., whether such trophic action is to be viewed as one of paralysis or as one of irritation. The clinical evidence points most strongly to the process being one of irritation. In the first place, cases of herpes are associated with neuralgic pain; in the next, a history of preceding neuralgia is very commonly to be obtained in cases of trophic keratitis, even though the cornea be anæsthetic at the time when the keratitis supervenes; thirdly, aseptic removal of the Gasserian ganglion, with healing by first intention, is not necessarily followed by keratitis even though the eye be not protected; and finally (and perhaps most important) cases are frequently met with in which a condition of iritis may precede the keratitis. As bearing on these points I will relate the following cases.

CASE 3.—A man, aged forty-one years, came to the hospital on Aug. 14th, 1897. The following notes were then made: "There is complete loss of sensation in the region supplied by the left fifth nerve; there is a shallow, non-vascular ulcer involving the entire extent of the left cornea with the exception of a narrow, clear zone at the outer margin, very slight ciliary injection, no facial paralysis." The patient gave a history of having previously had violent attacks of neuralgia in the left side of the head and eye. The edges of the lids were pared and sutured and the ulcer slowly healed, the cornea becoming much clearer. Later right facial paralysis with intense right-sided neuralgia supervened. Dr. Bastian, who saw the case, regarded it as one of syphilitic meningitis.

CASE 4.—The patient was admitted to University College Hospital under Dr. Bastian in November, 1897, suffering from the effects of an intracranial growth. He stated that the left upper eyelid had "dropped" in the previous September and had remained in that condition ever since. Examination of the left eye showed that there was complete ptosis, the eyeball was quite immobile, the cornea was clear with well-marked circumcorneal injection and deep anterior chamber, the iris was dull, the pupil was of medium size, reacting sluggishly to light; tension was full; and the cornea and conjunctiva were quite anæsthetic. On the right side there was paralysis of the external rectus but no affection of the cornea or iris or fifth nerve. There was optic neuritis in each eye. In addition to the paralysis of the left third, fourth, fifth, and sixth nerves there was paralysis of the left hypoglossal and difficulty in swallowing and in articulation. Eight days after admission a small central funnel-shaped ulcer was noted in the left cornea and there was some increase in the iritis; the eye was now kept effectually bandaged and the ulcer healed in the course of three or four weeks. The patient left the hospital a few days before he died and no post-mortem examination was obtained. The points of special interest in this case are: (1) the supervention of the keratitis in spite of the protection afforded by the presence of ptosis, though doubtless the latter modified and limited the extent of the ulceration; (2) the occurrence of a deep-seated inflammation—iritis—before the corneal trouble; and (3) the presence of irritative lesions (iritis and optic neuritis) at the same time that the cornea was insensitive, indicating that the trophic action is of the nature of irritation and yet may co-exist with paralysis of the ordinary afferent nerves.

CASE 5.—This patient, a woman, was in University College Hospital under the care of Dr. Bastian. On the right side the third, fourth, and sixth nerves were paralysed and there was anæsthesia over the right forehead down to the level of the palpebral fissure. The ptosis was not complete, about the upper half of the cornea being covered. In the lower half of the cornea was a superficial ulcer and above this a nebula, the horizontal upper edge of which corresponded to the edge of the drooped upper lid. There was and had been much neuralgic pain in the region of the fifth nerve. The eye was bandaged and improved a little, but there were repeated attacks of keratitis, always accompanied by severe fifth-nerve pain. The lids were, later, pared and sutured, with the result that the ulcer healed and no recurrences have taken place in the ulceration although the pain has continued. In this case the ptosis certainly modified the extent of the ulcer, but it is important to note that mere bandaging did not arrest the ulceration and also that irritation of the fifth nerve may exist with partial anæsthesia of it.

Ferrier[6] has published a somewhat similar case in which neuropathic keratitis was associated with "anæsthesia dolorosa" in the territory of the fifth nerve and he regarded the keratitis as due to irritation of the nerve. Hutchinson, too, states that the cases of herpes in which the cornea is affected are those most prone to suffer subsequently from neuralgia, and this post-herpetic neuralgia may persist for months after the vesicles have disappeared and may co-exist with complete anæsthesia of the cornea. Hence the presence of an anæsthetic cornea in any one case of keratitis does not render the assumption of irritative processes of a trophic nature going on at the same time at all unjustifiable. Chibret[7] has described cases of iritis and keratitis in which there were "tender points" over the spots of emergence of the branches of the fifth nerve—an observation familiar to most—but he especially described these cases because he found that massage applied to these nerves was quickly followed by marked improvement. I have not found, however, any confirmation of this last statement.

It has been suggested that the phenomena are due to vascular dilatation the result of stimulation of a sensory nerve; but that this is inadequate is shown by the occurrence of neuropathic keratitis with such variable condition of the sensibility of the cornea and also, that though preceding neuralgia is common, yet at the time of supervention of the keratitis anæsthesia is often present.

A review, then, of the clinical study of these cases of keratitis leads to the conclusion that the most likely explanation of them is that they are caused by perverted trophic action, such perversion being of the nature of irritation, the various other explanations suggested being inadequate to explain all cases.

Much experimental work has been done to elucidate the nature of the action of the fifth nerve on the nutrition of the cornea. Majendie (1822) first drew attention to the effect of section of the fifth nerve on the cornea and was followed by Bernard (1863), who showed that the effect was the more marked if the animals were young or diseased at the time. Meissner (1867) showed more or less accidentally that it was possible to divide one portion of the nerve—the inner—with the result of inducing keratitis without anæsthesia and conversely. Snellen (1857) and others tried to show that the results so obtained were merely due to slight injuries—desiccation, &c., of the cornea the direct result of the anæsthesia—and,

Digitized by Google

in order to explain how such slight injuries produced such severe corneal inflammation, assumed that the cornea after section of the nerve had a diminished power of resistance, an assumption which almost implies a nutritional change. Later Feuer[8] and Hippel[9] proved that an insensitive cornea does react in a normal way to injuries and thought that the essential factor in the causation of the keratitis was a too dry condition of the cornea. Samuel, Meissner, and especially Duval and Laborde,[10] have drawn attention to the occurrence of iritis and hypopyon *before* the corneal lesions after section of the fifth. The latter observers—confirming an earlier suggestion of Meissner—think that they have demonstrated a bulbar nucleus concerned with these trophic functions of the fifth nerve. Laborde,[11] too, has described choroidal changes developing after section of the fifth nerve exactly analogous to the changes described in some cases of facial hemiatrophy. Gaule[12] describes necrotic changes in the corneal corpuscles with epithelial proliferation after division of the ophthalmic nerve, and assumes that these corpuscles are the "end organs" of the sensory nerves and degenerate in consequence of the atrophy of the nerve. On the whole the experimental work supports the hypothesis of the existence of trophic fibres in the fifth nerve (as distinct from the fibres of ordinary sensation), and bearing in mind that many of those experiments, including Meissner's, were performed in the pre-antiseptic days and contrasting them with the favourable results which follow aseptic removal of the Gasserian ganglion in man they may be taken as indicating that the essential lesion of the trophic fibres is of the nature of irritation. Some few experiments have been done with the object of ascertaining if continuous irritation of a nerve is followed by changes in the tissue, and abscesses and ulcers have been described as resulting from such irritation. But I believe these experiments are generally discredited and in any case need confirmation. In whatever way Gaule's results are to be explained his experiments are of importance as showing that a direct relation does exist between the integrity of the fifth nerve and the essential structure of the cornea.

The lesions of the fifth nerve found associated with trophic keratitis are very various, and from the point of view of the lesion being of the nature of irritation it is important to note that the nerve is as a rule only partially damaged. In one of the earliest cases the Gasserian ganglion is described as yellowish-grey; in another recorded in 1833 it is said to be enlarged and lardaceous. Alison (1836) recorded a case in which the nerve was indurated both in front and behind the ganglion. Haase (1882) found softening in the anterior part of the pons with hæmorrhage into the ganglion. Mendel's case, previously referred to, was found to be due to softening of the upper part of the pons. In a case recorded by Bernhardt there was "superficial destruction of the pons" and changes in the corpora quadrigemina. Genkin[13] found in one case a gummatous tumour of the sphenoid compressing the fifth nerve. Schweinitz in a case of trophic keratitis dissected the ciliary nerves and found them to be normal. On the other hand, in a case of herpes the ophthalmic nerve was found by Wyss[14] to be inflamed, the Gasserian ganglion was surrounded by blood and infiltrated with pus cells, but the nerve on the proximal side of the ganglion was healthy. The changes in the nerve were regarded as indicative of true neuritis. Hæmorrhage and degenerative change in the Gasserian ganglion have been found in other cases of ophthalmic herpes. Baudry[15] relates two cases: in one the nerve was damaged by a fracture of the petrous bone and in the other the corneal changes were consecutive to a neuralgia of the fifth nerve induced by cold. In a case under the care of Mr. Tweedy the nerve and ganglion were found post mortem involved in a large sarcomatous growth.

From the above considerations it seems fair to conclude that the nutrition of the eyeball is directly dependent on the integrity and condition of certain nerve-fibres contained in the Gasserian ganglion and ophthalmic nerve, and that irritation of these fibres leads to those changes in nutrition of the cornea which are recognised as neuropathic keratitis. As to the exact *modus operandi* of such irritation little can be said. The best known effect of nervous stimuli on the structure of organs is that produced by stimulating the secreting nerve of glands. Now, the nutrition of the eyeball is dependent largely on the fluids derived from the ciliary body and within the last few years structures resembling glands have been described in the ciliary processes and those glands have been found enlarged and showing increase in their epithelium in cases of "serous iritis," a condition characterised by increase of aqueous humour and alteration in its composition, as evidenced by the presence of keratitis punctata. It seems possible that the trophic nerves of the eyeball may be the nerves which supply these glands and that abnormal stimulation of them may lead both to an increase in the fluid secreted and an alteration in its composition. In support of this suggestion I would recall the fact previously cited, that frequently in experimental investigations hypopyon precedes the occurrence of keratitis, and a similar sequence may be observed clinically; and also that stimulation of the fifth nerve, as in some cases of trigeminal neuralgia, leads to increase of tension and a deepening of the anterior chamber. Further, the facts alluded to in discussing facial hemiatrophy tend in the same direction. But at the same time it must be allowed that the connexion between the nerves and the integrity of the cornea may be more direct and intimate than this, and although such connexion has not been definitely proved, yet the occurrence of discrete herpetic vesicles on the cornea and the degeneration of the corpuscles after section of the nerve make such a supposition quite possible.

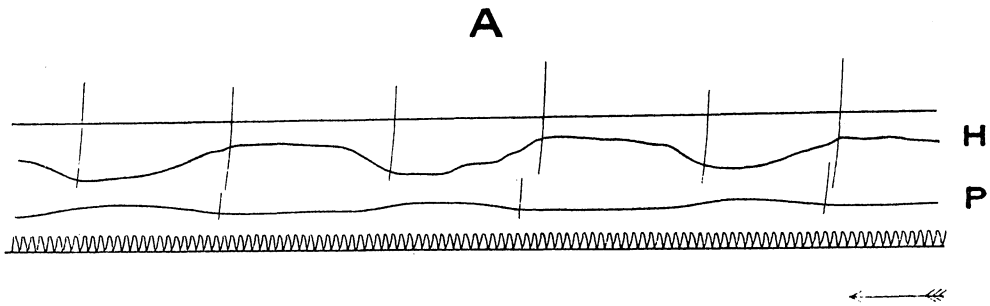
ON THE HEART-RADIAL INTERVAL AND A HITHERTO UNKNOWN METHOD OF COMPENSATION IN AORTIC REGURGITATION.

BY PAUL M. CHAPMAN, M.D., F.R.C.P. LOND.,
PHYSICIAN TO HEREFORD GENERAL INFIRMARY.

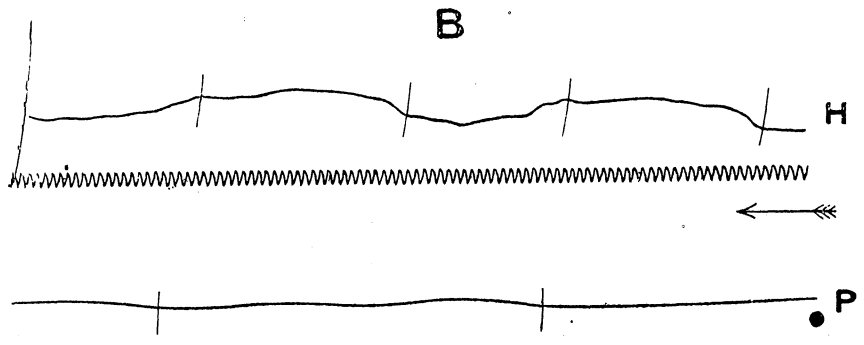
IN the Goulstonian lectures, published in THE LANCET in March, 1894, I criticised at some little length the possibility of the abolition of the "præsphygmic interval" in cases of pure and uncomplicated aortic regurgitation, and I made the following statement, which I believed to be thoroughly justified on physiological grounds, and to be in accordance with my own experimental observations: "In his preliminary chapter on the 'Variations of the Præsphygmic Interval in Disease' Keyt gives as his first proposition that 'the præsphygmic interval is abnormally shortened in free aortic insufficiency,' and I think that this proposition, confirmed as it is from independent sources, is one that should be admitted. He with a positiveness which almost calls up antagonism, says 'the testimony is ample and complete and establishes the fact beyond question.'" This statement I have now to traverse, and, indeed, I am about to show, and by the graphic method which he considered to be incontrovertible, that the heart-radial interval may be excessively increased in pure aortic regurgitation.

In a normal heart no blood can flow from the ventricle into the aorta until the pressure within the ventricle has risen above the aortic blood-pressure; until this time the aortic valves must undoubtedly remain closed. The time during which the intraventricular pressure rises during systole is called the "Anspannungzeit" or (by Keyt) the "Præsphygmic Interval." Keyt says (p. 165): "When the aortic valves are permanently open the pressures in the ventricle and aorta are always in equilibrium at the beginning of systole (the two cavities being in one), whether the mean pressure be low or high. In consequence of this oneness or equilibrium of pressure the heart's impulse and aortic pulse will be synchronous." With regard to this, I always thought that the often confused ideas of blood-flow and of pulse-wave, two wholly different things, were not sufficiently differentiated in Keyt's mind. Even an impact against a *closed* valve may conceivably send on a *wave*, though no fluid pass through the valve. Whether this is so or not in an acting heart I am not prepared to show. It is not likely, and it is not to



Digitized by Google

my present purpose. Keyt's statement that the "præsphygmic interval" is abnormally shortened in free aortic insufficiency—is, indeed, *always* shortened in pure aortic insufficiency—is based on his graphic method, which he thinks conclusively proves that in every case of aortic insufficiency there is diminution or abolition of the *heart-radial* interval. The theory of abolition of præsphygmic interval he calls to his aid in explanation of his facts, and henceforth "the testimony is ample and complete and establishes the fact beyond question." To him experiment and argument certainly went hand-in-hand.



His facts were, however, clinically speaking, new. Before the graphic method various clinicians thought otherwise. Dr. Henderson in 1832 stated that the interval between the heart's impulse and the arterial pulse was prolonged in aortic insufficiency. Flint says that the fact of prolonged delay "is not to be denied" (1859). Walshe says: "The retardation may with care be detected in many, but unquestionably not in all, cases of that disease." Many principal authorities have held the same view. The latest and not the least careful observer, whose deliberate clinical statements are not to be lightly denied, Sir William Broadbent, says[1]: "The pulse in aortic regurgitation is always retarded or delayed—that is, there is an appreciable interval between the beat of the heart or the carotid pulse and the pulsations in the radial artery which varies according to the extent of the incompetence. This delay is due partly to the collapsed and empty state of the arteries between the beats and partly to their large size and loss of tone. There is no longer a continuous column of blood between the heart and the periphery, and the tension in the arterial system has to be considerably augmented by the launching of a large volume of blood into the aorta before the vessels are rendered sufficiently tense for a pulse wave to be transmitted."

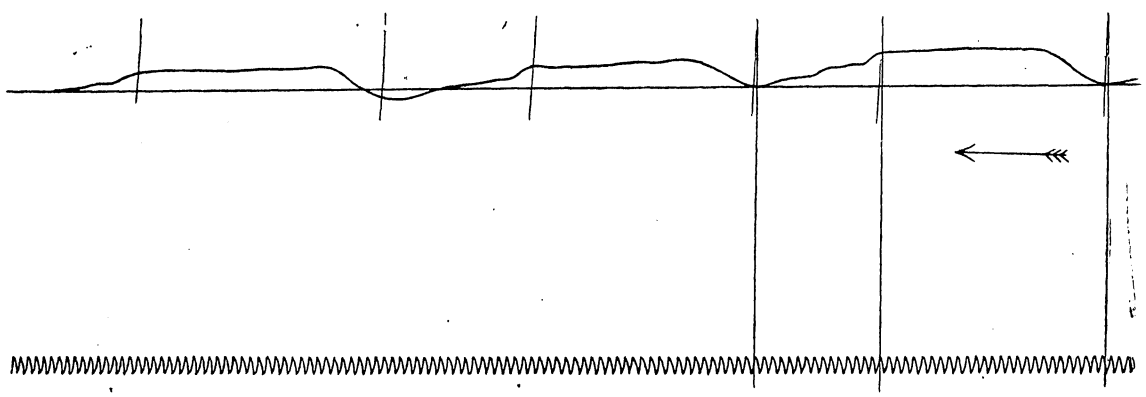
Yet Keyt and purely theoretical physiology are not alone in stating that the heart radial interval is diminished. François Franck made observations on patients affected with aortic insufficiency and first presented his results to the Société de Biologie in March, 1878. He states as the conclusion of his researches: "In large, pure aortic insufficiency the retardation of the pulse on the beginning of the systole of the heart is very notably diminished." I cannot hope to completely and for ever decide this question, but I can at least give some evidence in favour of the great clinicians, though differing from Sir Wm. Broadbent as to the explanation of pulse delay in these cases.

In the first place, though I greatly admire Keyt, I must enter some protest against a paragraph of his which I am sorry he ever wrote. He says (p. 165): "It is easy to explain the fallacy of an exaggerated delay of the pulse on the systole of the ventricle in aortic insufficiency; the enlarged ventricle suddenly filling from both the aorta by reverse and the auricle by direct flow communicates a shock so marked as to be mistaken for systole. This impulse occurring in the first part of diastole and preceding the arterial pulse at such distance gives the impression of enormous delay of the pulse. ..... The fallacy arose from an error of observation which the graphic method was needed to correct." This is to attribute an almost laughable incompetence to the great names I have cited and calls for no comment. I did, however, as the result of some of my own observations, think Keyt was safe in the position he was trying to defend. One such case I published in the lectures aforesaid and I thought his proposition should be admitted. I have now to publish a case of pure and uncomplicated aortic regurgitation which demonstrably in a particular instance proves the reverse, and which therefore completely upsets his doctrine.

Tracing obtained in February, 1898. Systole 0·40 sec Diastole 0·36 sec. Heart radial delay 0·53 sec. Pulse rate 80. H, Heart. P, Pulse. Reed chronograph vibrating 64 per second.

A second tracing in the same case as A, but at increased speed.

The patient was granted six months' leave from his employment owing to a breakdown in health and was placed under my care in January last. He was then in an imminently precarious state, with much cardiac distress, and was subject to some curious cerebral sensations which he could scarcely describe. The heart was dilated and presented a loud and solely regurgitant aortic murmur, accompanied by a characteristic pulse. Being of a rather plethoric habit he was put upon careful dietetic treatment with the object of reducing his plethora and the heart condition was treated with strychnine and strophanthus. Living at a distance he was seen only at intervals of a fortnight, but early in February the accompanying tracing (A) was obtained by the transmission apparatus which is fully described in my Goulstonian lectures, some considerable improvement in his symptoms having already taken place. The chronographic simultaneous tracing was taken from a harmonium reed vibrating 64 times in a second, the accuracy of which had been recently tested. The first obvious result of the tracing is to show a very



[1] Heart Disease, 1897, p. 142.

Digitized by Google

marked heart-radial delay—a delay of 0·53 second—whereas the normal heart-radial delay is about from 0·17 second to 0·2 second. Another striking result is the encroachment of systolic on diastolic time, the systole being of 0·40 second duration and the diastole varying from 0·36 second to 0·39 second. Although the cardiograph was in excellent working order the upstroke at the beginning of systole is seen to be a slow upheaval manifesting itself in an oblique line. The simultaneous pulse tracing was obtained with difficulty; unlike a normal tracing it is comparatively unformed, though the commencement is sharply defined and easily measurable. On March 11th a second tracing (C) was obtained. The patient was subjectively in a much better state of health, though still complaining of strange sensations at the top of the head. The initial slow upheaval in the cardiac tracing is still more clearly seen. The heart-radial delay was 0·4 second. The pulse-rate was 70. The duration of systole—which for that pulse-rate should be from 0·32 second to 0·33 second—was 0·50 second, the diastolic rest being 0·33 second.

With regard to the increased heart-radial delay I think the following explanation seems to be the correct one. That in a sound and normally acting heart there is a definite "Anspannungzeit" or "præsphygmic interval" is not to be questioned. It is based on absolute experiment and does not admit of doubt. The rise of pressure at the beginning of systole is, however, quick owing to the initial low blood-pressure within the ventricle, and the contraction is therefore a sudden thing. In pure aortic regurgitation, however, it is not to be doubted that the intraventricular blood-pressure is already great at the commencement of systole. To lift a 5 lb. weight in the hand upwards in order to strike a drum may be a matter of a moment and the resulting impact may be sudden and great; to raise a weight of 50 lb. the same distance would take longer, while the impact against the drum need not be greater than in the first instance. In pure aortic regurgitation it is perhaps not too much to assume an analogy with the act of lifting the larger weight. The contraction is therefore comparatively a very slow contraction and that this is so can be plainly seen in the cardiac tracing. The first condition

C

Same case as A and B on March 11th, 1898. Heart radial delay 0·40 sec. is not shown in the tracing. Systole 0·50 sec. Diastole 0·33 sec. Pulse rate 70.

I have elsewhere shown that normally, whatever the pulse-rate may be, the diastolic rest exceeds the systolic labour. At a pulse-rate of 70 there should be 15 hours and 5 minutes of rest to 8 hours and 55 minutes of work. Here there is about 14¾ hours of work to 9¼ of rest. As far as I know this kind of compensation for any form of heart disease has not even been surmised. Encroachment of systolic on the diastolic time has not been brought about by physiological experiments either by increasing the blood-pressure or by varying the rate of heart beat or by any like means. In a paper in the Transactions of the Royal Medico-Chirurgical Society, vol. lxix., 1886, on Cardiography I endeavoured to show that while digitalis slowed the heart and regulated an irregular heart, yet it did not lengthen the relative duration of systole, while, on the other hand, convallaria appeared to have the property of really somewhat lengthening systole—that is to say, lengthening it at the expense of diastole. However immediately beneficial this form of compensation may be, by means of maintaining the pressure in the arterial system and thereby avoiding the sudden and futile dilatation arising from the rapid ingestion of a large volume of blood into comparatively empty vessels (the pressure in the arteries varying from perhaps 60 mm. Hg. at the end of diastole to 200 mm. Hg. during systole), yet it cannot be doubted that eventual exhaustion must take place at an early age and the heart's mechanism be worn out by excessive work long before the natural and normal term of life. Should there be truth in the suggestion that convallaria lengthens the relative duration of systole it might be advisable to administer it in cases where this kind of compensation is lacking, in preference to giving digitalis, which does not lengthen the relative duration of systole but slows the heart by increasing diastole, at the same time supporting the ventricle, increasing its force and regulating its action, as well as regulating its action in regard to diastole. A possibly superior merit of strophanthus may lie in its not contracting the arterioles as does digitalis, with the consequence of permitting freer outflow of blood through the arterioles.

of the heart-radial delay is therefore produced. Secondly, the pulse wave arising from the slow contraction of the ventricle is consequently a slow wave, and can only be rapid when the arteries are comparatively empty and the ventricular pressure slight at the commencement of contraction. While, therefore, clearly recognising in normal hearts the presence of an "Anspannungzeit," or what is termed by Keyt a "præsphygmic interval," and acknowledging to the full the necessity and value of its recognition, it does not follow that its abolition necessarily entails a shortened heart-radial interval. It might either be desirable to retain the term "Anspannungzeit" or to create some more convenient term. The preparation to action by rendering the harness tense may in pure aortic regurgitation not be possible—the poor horse (in this instance the heart) being already under a steady stress from the outset. The term "præsphygmic interval," which owing to the meaning given to it by its creator unfortunately presumes a special theory, should certainly be thrown aside in favour of some other term which will not implicitly commit us to theories as to what will happen in its absence.

I would suggest the use of the term "isodynamic interval" to express this period of time *which in aortic regurgitation may be abolished without lessening the heart-radial interval.* Or to those who prefer it the term "prokinetic interval" may perhaps commend itself. The first term suggests the time of activity occupied in attaining balance of blood-pressure, the second the time of activity antecedent to the onward movement of blood. Of the two terms the first appears to me to be the least compromising. Its employment in electromagnetics is too far afield to lead to confusion, and used here it would be a containing term where the desired sense did not overflow the margin. Moreover, I think it better to be able to say in the instance I have been discussing not that an "Anspannungzeit" or "prokinetic interval" did not exist, but that an isodynamic condition prevailed from the beginning of contraction.

THE DIAGNOSTIC USES OF PERCUSSION OF THE VERTEBRAL SPINES, WITH GENERAL REMARKS ON "PLEXIMETRIC" BONES AND VISCERA.[1]

BY WILLIAM EWART, M.D. CANTAB., F.R.C.P. LOND.,
PHYSICIAN TO, AND JOINT LECTURER ON MEDICINE AT, ST. GEORGE'S HOSPITAL; PHYSICIAN TO THE BELGRAVE HOSPITAL FOR CHILDREN; EXAMINER IN MEDICINE AT THE CONJOINT BOARD.

PRACTICAL importance attaches to percussion of the spinous processes, though I have never seen it carried out. It is both easy to perform and very definite in its results. Normally the spine is always resonant from the occiput to the coccyx. The slight variations in the degree of this resonance which belong to different levels are matters for finer percussion. The occurrence of any considerable dulness anywhere in the length of the spine is therefore in itself highly suggestive. The normal vertebral resonance is a borrowed resonance, living bones being naturally dull. Its pleximetric character may be easily demonstrated in various ways, as, for instance, by the fact that a considerable pleuritic effusion does not render the spines dull, the conducted resonance from the sound side, and perhaps from the compressed lung, prevailing over the dulling influence due to the fluid. Localised spinal dulness thus indicates local causes isolating the vertebræ at least partially from their usual plentiful supply of resonance, and we cannot expect slight causes to bring it about. All the greater, therefore, is the significance attaching to any marked dulness. This pleximetric conduction of distant local dulnesses is of value since it conveys to us information from an otherwise inaccessible depth (measured by the long axis of the vertebra) as to mediastinal conditions which may be of the first importance. Thus, at different levels in the chest it may afford evidence of upper thoracic glandular enlargements, or of aneurysm of the arch, or of œsophageal disease, or of infra-tracheal glandular swelling, or, lastly, of pericardial effusion, the "lower dorsal dull patch," which is an invariable accompaniment of the latter, always including dulness of the eleventh and twelfth spines.[2] Lower down abdominal and pelvic disease may in the same way be indicated by local dulness as may be described in a future communication. For surgical diagnosis this method is likely to be of advantage. Mere infiltration of the vertebræ with cancer or tubercle would probably not modify their conveyed resonance; but spinal abscess, extensive outgrowths, tumours, &c., might dull the percussion note. My observations on these points are not yet completed, but I have already found this method of considerable use in the diagnosis of œsophageal disease and of mediastinal glandular enlargements in the interscapular region. The same conducting power for vibrations belongs more or less to all the thoracic bones. Three of them, however, are more specially "pleximetric" bones—the clavicle, the sternum, and the scapula, and concerning them there is much to be said. Further remarks on this subject and on that of the pleximetric resonance of viscera will be found elsewhere.[3] I would merely draw attention here to the scapula, which plays the part of a huge pleximéter. This is a leading fact not sufficiently recognised in dorsal percussion. In spite of the great thickness of its muscles the scapula is often the most resonant part of the back, as a comparative percussion outside its borders and within them will show. This resonance which tends to be uniform over the scapula as a whole is derived from the underlying resonant thoracic surface, and it is also propagated along its spine to the shoulder. It thus happens that the acromion, although far removed from the lung, is resonant.

Pleximetric viscera.—The simplest example of a pleximetric visceral resonance is that sometimes afforded by the spleen. Under the influence of gaseous distension of the stomach and of the colon the spleen may become not only resonant but tympanitic, and the "boxy" note which it yields will then enable us to determine its size with as much accuracy as when the customary dull note is our guide. This is of practical importance to the physician, who will sometimes have to decide whether the abnormal resonance at the axillary base is an extension of Traube's area and due to a stomach distended upwards, or whether it is due merely to a pleximetric resonance of the spleen.

The ordinary resonance conveyed to the left lobe of the liver from an inflated stomach is too well known to need comment. Gastric inflation may also impart a tympanitic resonance to the lower part of the præcordium. When these abnormal resonances attain an unusual degree collateral evidence and additional physical signs will generally help us to determine whether they may be due to an intra-peritoneal gaseous accumulation.

Of special interest to the surgeon is the pleximetric resonance sometimes assumed by the right lobe of the liver, simulating the presence of gas in front of that lobe. The most striking case of this sort was one in which opinions were divided as to the origin of the supposed gaseous extravasation. Mr. H. W. Allingham, who operated, failed to discover any lesion in the ileo-cæcal region and made a second incision in search of the gastric lesion which I had suspected. There was no free gas in the peritoneum and the most exhaustive exploration did not succeed in tracing any disease. The symptoms not having been relieved the patient died. The cause of the tympanitic resonance of the hepatic region was revealed at the necropsy. A limited gaseous abscess, due to a gastric ulcer, was closely bound down between the liver and the diaphragm. It was situated so far back that until the liver itself was removed it had escaped detection at the preliminary examination of the parts *in situ*. This was a clear instance of complete pleximetric resonance of the liver due to an underlying collection of gas confined under pressure. The case is instructive as an illustration of the difficulty of diagnosing this conveyed tympanitic resonance from that which arises from a gaseous accumulation between the liver and the parietes.

COBRA POISON IN RELATION TO WASSERMANN'S NEW THEORY OF IMMUNITY.

BY WALTER MYERS, M.A., M.B., B.SC. CANTAB.
(From the Pathological Laboratory, Cambridge.)

IN a paper read before the Pathological Society of London in April last I gave a short account of some experiments on the antidotal properties of normal tissue emulsions in regard to cobra poison. I was led to undertake the experiments by a consideration of Wassermann's work which was based upon a theory of Ehrlich,[1] according to which every "antitoxin-producing" toxin is specific in the sense that it produces its symptoms by chemical combination of its toxophoric atoms with some cell substance in the body of the susceptible animal. If this is the case then, as Wassermann argued, it is clear that on mixing the toxin and the specific cell substance *in vitro* the toxin should be neutralised; and, indeed, a suitable mixture of tetanus toxin and emulsion of spinal cord substance derived from a susceptible animal is harmless to mice and even to guinea-pigs. On this observation Wassermann[2] based his theory of "Seitenketten-Immunität," according to which a toxin is neutralised (*a*) *in vitro* and (*b*) *in corpore* by saturating its toxophoric atoms with those cell substances for which these atoms have a specific affinity. By the term toxin is meant that class of poisons against which an immunity may be established by repeated injection under suitable conditions and which then lead to the appearance of specific antitoxins in the blood of the immunised animal.

The method I employed in testing the antidotal properties of normal tissues was to emulsify the various organs of a susceptible animal—the guinea-pig being used in most cases—with

[1] Werthbemessung des Diphtherieheilserums: Klinisches Jahrbuch, 1897.

[2] Berliner Klinische Wochenschrift, 1898, No. 10.

Digitized by Google

physiological saline solution, to mix the emulsion with the cobra poison, and then to test the action of the mixture on guinea-pigs. For inoculation guinea-pigs also were employed, weighing between 250 and 350 grammes. For such animals the minimal certainly letha dose was 0·1 milligramme of the dried venom. In these experiments 0·15 milligramme was injected, a dose which causes death of the controls in from two to three hours.

Cobra poison belongs to the class of toxins as above defined and contains at least two toxic substances. One of these is hæmolytic—i.e., it alters the red blood corpuscles, setting free the hæmoglobin they contain; the other is a nerve poison, which probably acts on the respiratory centre, and possibly also on other parts of the nervous system. Therefore I made a considerable number of experiments on various parts of the nervous system—e.g., the medulla, the cerebral cortex, and the spinal cord of the guinea-pig and the bullock. The toxicity of cobra poison is not, however, perceptibly altered by mixture with an emulsion of any part of the nervous system or by mixture with the blood or the serum of a susceptible animal. Calmette [3] independently has made similar experiments with the brain of the rabbit and of Bothrops lanceolatus and has obtained similar results. The liver, too, was subjected to a careful examination, because of its action on certain alkaloids [4] and also because of the impunity with which enormous doses of snake poison may be given *per os*. Moreover, as Fraser [5] has recently shown, the bile of various animals prevents death when injected simultaneously with this poison or even subsequently into the opposite side of the body. However, in no case did I succeed in averting or delaying death by the injection of liver emulsion with the venom. On one or two occasions I found that if a solution of poison be added to liver substance, and the mixture be ground up and allowed to stand for twenty-four hours, on injection of such a volume of the supernatant fluid as should contain a lethal dose the animal survives or dies after a longer interval than the control. But even by this method a positive result is not constant and the fallacy of assuming that the poison is equally diffused throughout the mass is obvious. When a certainly lethal dose is added to liver substance already emulsified with saline solution injection of the mixture leads to death with the same symptoms and in the same time as pure cobra poison alone. I have therefore not been able to confirm Professor Kanthack's [6] observations, that liver extract has a marked retarding influence on the action of cobra venom. But Professor Kanthack himself confesses that in one case where he was working with the liver extract of a young rabbit he had obtained no antitoxic effect.

The suprarenal capsules were indeed the only organs which invariably influenced cobra poison. With emulsions of bone-marrow, kidney, lymphatic gland, muscle substance, ovary, spleen, testicle, thymus, uniformly negative results were obtained. In my first experiments on the suprarenals I used those of the guinea-pig and found that in most cases the animals survived, and when death occurred it was considerably delayed. I then tried the suprarenals of the sheep and bullock and found that when fresh they invariably prevented death. *The medulla is inactive in this respect, the cortex alone protecting.* This, then, is probably the explanation of the variancy in the results with the guinea-pig's suprarenals which I occasionally obtained. For in these animals not only are the capsules small but they consist almost entirely of medulla. Rabbits' and sheep's suprarenals also protect.

I then tried the action of tabloids of various organs, using the preparations of Messrs. Burroughs, Wellcome and Co., and found here too that the suprarenal tabloids alone had any action, though the effect of the tabloids is less certain than that of the fresh glands.

This action then of the suprarenals is not shared by any other organ in the body and this fact alone suggests that mechanical precipitation of the poison is not an important factor of their protective power. And as injection of the suprarenal emulsion either mixed with the poison on the same side or by itself on the opposite side of the body alike prevents death, mechanical action, if it even occurs, must play but a very small part. And since, even when administered in large quantities, they only influence amounts of poison just above the minimal lethal dose, and cannot protect against multiple doses, we must conclude that they do not contain an antitoxin, that is, a substance which neutralises the poison *in vitro*.

The suprarenal cortex, then, of susceptible animals contains another of those substances, such as bile salts, cholesterin, tyrosin,[7] which somehow raise the natural resistance of the animal and so prevent death from doses slightly above the minimal lethal. It is noticeable too that the body of the animal most susceptible to cobra poison—viz., the guinea-pig—contains no substance which will combine with this poison *in vitro*, as Wassermann and Takaki [8] and others have found for tetanus, and more recently Kempner and Schepilewsky [9] for the "Botulismus-gift." Whether Wassermann's theory will prove valid or not for all toxins with a measurable incubation period at least it does not agree with the facts above summarised for poison.

SOME REMARKS UPON A NEW MYDRIATIC.

BY SYDNEY STEPHENSON, M.B., C.M., F.R.C.S. EDIN.,
OPHTHALMIC SURGEON TO THE EVELINA HOSPITAL AND TO THE NORTH-EASTERN HOSPITAL FOR CHILDREN, ETC.

THE claims of ephedrine hydrochloride as an agent for dilating the pupil have been before the profession for several years, but apparently without attracting anything like general attention. The first communication upon the subject was made by a Japanese physician, Kinnosuke Miura,[1] and this was soon followed by papers from the pens of J. Inouye [2] and A. de Vriese.[3] From these contributions, however, it was clear that the dilatation of the pupil induced by ephedrine was of moderate extent only, although it possessed the great practical advantage of passing off rather quickly (in from 1 to 20 hours). Later it was found that the action of ephedrine could be enhanced by the addition of a trace of homatropine hydrochlorate in the proportion of a hundredth part of the latter to one part of the former substance. This observation led E. Merck, the well-known Darmstadt pharmacist, to combine the two medicaments. The new agent, which is known as "mydrin," is a white powder, readily soluble in water. Its physiological action has been reported upon by Groenouw [4] in Germany, by Suker [5] in America, by Cattaneo [6] in Italy, and by Mr. Simeon Snell [7] in this country. These various observers find that a 10 per cent. aqueous solution when dropped into the eye has the power of dilating the pupil moderately within a few minutes, without affecting accommodation in the least. They also agree that the action of the pupil to light is to some extent retained while the eye is under the influence of the drug, the effects of which pass away within from 4 to 6 hours. In no instance have they seen any irritation or inflammation result from the application. Groenouw, who experimented on 100 patients, found that the dilated pupil had an average diameter of 5·6 mm. Suker speaks of mydrin as "an ideal mydriatic for diagnostic purposes," and Mr. Snell's experiences appear also to have been equally favourable.

These claims seemed to me too strong to be set on one side without investigation. Accordingly for some time past I have used a 10 per cent. watery solution of mydrin for the purpose of dilating the pupil, when I wished to explore all parts of the fundus oculi with the ophthalmoscope or to examine the cornea carefully in order to ascertain the presence or absence of slight changes. Moreover, for the

Digitized by Google

purposes of more exact study I have recently taken 20 patients and noted in each one (*a*) the near and distant sight, and (*b*) the diameter of the pupil. A single drop of mydrin solution (10 per cent.) was then placed in the conjunctival sac, after which the following points were observed: (*a*) the time at which the pupils became dilated; (*b*) the transverse diameter of the pupils; (*c*) the near and distant vision; and (*d*) the time at which mydriasis passed away.

The results obtained in this way may be thus briefly related. The pupil became dilated in a period which varied, according to the individual, from 15 to 68 minutes, the average of the 20 observations being 29·35 minutes. The mydriasis was found to ensue more speedily if patients kept their eyelids closed after the application had been made. Owing to the fact that the iris did not completely lose its action to light, there was some little difficulty in measuring the size of the dilated pupil, the transverse diameter of which ranged from 5 to 7·5 mm., and averaged 6 mm. For a similar reason it was not altogether easy to say with precision when mydriasis had passed away. But in no instance did the maximum time (after full dilatation) exceed 4 hours, while the minimum stood at 75 minutes. The average worked out at 184·84 minutes—that is to say, a trifle more than 3 hours. In no case did sight, either for distant or near objects, show any alteration when the eye was fully under the influence of mydrin, a remark which applies also to the position of the punctum proximum. Lastly, it is practically important to note that the agent set up neither discomfort nor irritation.

As the result of my observations I have reached the conclusion that mydrin is capable of doing all that writers have claimed for it—namely, that it causes a moderate dilatation of the pupil without involving the function of accommodation. It cannot but prove, therefore, a valuable agent in the hands, not only of the ophthalmic surgeon, but also of the physician, who must often be desirous of exploring the fundus oculi with a dilated pupil.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum allorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

ROYAL FREE HOSPITAL.

A CASE OF MALIGNANT PUSTULE; DEATH; NECROPSY.

(Under the care of Mr. E. W. ROUGHTON.)

THE methods by which persons become infected by communicable diseases are often obscure, but in the following case it is practically certain that the patient was infected from one of the hides with which he was working. Attempts have been made to destroy the bacillus anthracis in bales of material which may contain it, and these attempts have been very successful in the case of wool, for it may be subjected without damage to a temperature sufficiently high to kill the bacillus, but hides are spoilt by this treatment, and, so far as we are aware, no satisfactory practical method exists of rendering hides which have been taken from diseased animals absolutely free from power of infection. The negative result of the culture from the blood is hardly sufficient to prove that no bacilli had entered the blood stream; in many of the fatal cases death is due to absorption of toxins and not to the presence of the bacilli in the blood. For the notes of the case we are indebted to Dr. R. P. Williams, house surgeon.

A man, aged fifty-three years, was admitted to the Royal Free Hospital on April 29th complaining of a sore and swelling of the right side of the neck. The patient was a blacksmith employed at the General Parcels Post Office, Clerkenwell. On April 26th he was engaged in mending Parcel Post baskets with strips of raw cowhide. The cowhides are imported from various parts of the world and are chosen by a Government inspector. The particular hides which the patient was using probably came from Rangoon or Zanzibar. He noticed a pimple on the right side of the back of his neck on the 27th and he scratched it. It did not trouble him till the night of the 28th when he found a swelling round a small sore in the original situation. On the following morning (the 29th) he felt so ill that he had to cease work and he was directed to go to his medical attendant, who sent him on to the hospital.

On admission the patient was found to have a typical malignant pustule situated on the right side of his neck. The brawny œdema extended above to the parotid and below to the right clavicle. On microscopic examination of the serum from the vesicles anthrax bacilli were found in large numbers. His temperature was normal. Mr. Roughton operated on the same day, excising the pustule and the skin for 1½ in. around it. The wound was swabbed with pure carbolic acid and left open, being dressed with cyanide gauze soaked in a 1 in 1000 biniodide of mercury solution. This was changed every four hours.

After the operation the temperature rose from normal to 99·2° F. and at 10 P.M. it reached 101·8°. The patient had no sleep during the night and in the morning the œdema had spread down the right side of the chest. The temperature fell to 100° in the evening (the 30th) and he vomited several times. Two bluish patches were noticed in the skin below the right clavicle. These gradually spread, the œdema itself also spreading to the left side of the chest and down towards the pelvis. No diarrhœa was present. The patient gradually became collapsed and, in spite of stimulants, died at 1 P.M. on May 1st.

At 10 P.M. on April 30th two cultivations on gelatin were made from the blood, one from the left index finger and the other from the œdema on the chest. No anthrax bacilli were found in either tube.

Necropsy.—At the post-mortem examination the vessels of the pleura and the intestines were injected but no other gross pathological condition was found.

ANCOATS HOSPITAL, MANCHESTER.

TWO CASES OF ECTOPIC PREGNANCY; RECOVERY.

(Under the care of Mr. STANMORE BISHOP.)

THE following two cases show clearly the benefit of early surgical treatment in ectopic gestation. The older methods, such as electricity, are being discarded, and it is more and more recognised that the best results are obtainable by early laparotomy. The operation should be performed as soon as the diagnosis is made with any fair degree of probability. Delay of even a few days may lead to a fatal issue.[1]

CASE 1. *Hæmatocele in Douglas's pouch; enlarged perforated Fallopian tube containing a clot; probable ectopic pregnancy; cœliotomy; recovery.*—A married woman, aged twenty-eight years, was admitted to the Ancoats Hospital on Sept. 14th, 1897. She had been married for eleven years and had had four confinements and one miscarriage. Her father died at the age of thirty-seven years from fever and her mother died at the age of sixty-five years from pneumonia. Nine of her brothers were dead; the causes of death were not known; two sisters and one brother were alive and in good health. The patient had always been healthy up to the time of her marriage. Her first labour occurred ten years ago; instruments were used, but there was no trouble with the placenta. She got up well, the child living. Her second labour occurred nine years ago; it was easy and her convalescence was normal; the child died from meningitis due to a fall. Her third labour occurred six and a half years ago; it was easy and her convalescence was normal, the child living. Her fourth labour (a miscarriage at three months) occurred five years ago. She got up well, had one period, and then became pregnant again. Her fifth labour occurred four years ago; the pregnancy was normal; the confinement lasted five days and no forceps were used. She was attended by a midwife and had never been well since. She noticed pain in the left iliac region before getting up. She was in bed for two months and pain had been intermittent ever since. The pain never occurred on the right side. The left leg had been painful and aching, but not

[1] American Journal of Obstetrics, April, 1895.

Digitized by Google

swollen. She had had much general swelling of the abdomen. Her periods had been regular since her last confinement to July, 1897. Then she was nearly eight weeks without any loss. At the end of August bleeding began and had never entirely ceased up to the date of her admission to hospital. On the first day she passed a clot but no formed material, shreds, or membranes since, passing nothing but blood or bloody fluid. Urination and defecation were normal. The appetite was feeble. There was no vomiting. Sleep was interrupted by pain of a gnawing character. The pain came suddenly, lasted for five or six hours, and went off gradually. During the pain the discharge increased. The temperature was 100·2° F. on admission. There was some pain on fully extending the left leg.

On Sept. 26th the temperature had fluctuated between 97·4° F. and 99° since admission. On vaginal examination the os was found to be split and the cervix open. The sound passed forwards at a normal length. The uterus was in the median line. Behind in Douglas's pouch there was a soft, elastic mass from which the uterus could be partially separated and which extended mostly on the left side. The broad ligament was palpable on the right side, but could not be defined on the left. The patient was a short, stout, healthy-looking woman. The diagnosis was a doubtful one—either pyosalpinx or ectopic pregnancy—but the weight of probability seemed in favour of the latter. The temperature between Sept. 26th and Oct. 4th, the date of operation, was more uniformly normal than it had been at any previous time, never rising above the normal line or descending below 97·6° except on the morning of the 4th, when it was 97·2°. There was no sudden pain or collapse.

On Oct. 4th cœliotomy was performed. The patient was placed in the dorsal position. On the right side there was a small multilocular cyst of the ovary of the size of a cricket-ball; this cyst was removed. On the same side the Fallopian tube was closed and swollen; the fimbriæ had disappeared. This was also removed and the stump was sewn over. Below in Douglas's pouch there was a collection of black clot weighing about 5 oz. which was cleared out by hand and sponges. The wall was cleared as much as possible of rough fibrinous material. The cavity containing this clot was roofed over by loosely adherent intestine and the spread-out left tube, which was much enlarged, and contained an adherent semi-decolourised clot, situated rather outside the middle of the tube. The tube had given way near its uterine extremity. All these parts were fixed by adhesions which yielded readily. The abdomen was closed by a triple suture and was sealed by celloidin. No flushing or drainage was employed. There was no great amount of shock. The operation was over about 1 P.M.

Calomel was given in grain doses every hour, commencing two hours after the operation; seven doses were administered. The patient had nutrient enemata every two hours. As there was a great amount of pain a ¼ gr. morphia suppository was inserted. The catheter was used at 5.30 P.M. and 6 oz. of urine were drawn off at 7.15 P.M. As no flatus had passed by 12.30 A.M. 3 gr. of sulphate of magnesium were given, but were immediately vomited. A sulphate of magnesium enema was given at 11 A.M. on the 5th. The bowels were moved at 6.15 P.M., 6.30 P.M., 8 P.M., and 9.15 P.M. on the same day. There was a little vomiting after the action at 8 P.M. but not afterwards. On the 6th at 3 A.M. a bloody discharge appeared *per vaginam*, but it was never excessive. It gradually decreased until the 8th. No shreds or definable masses were discharged. At 10 A.M. the nutrient enemata were stopped and feeding by the mouth was begun. On the 6th she passed a small amount of urine naturally at 10 P.M., but the catheter was again required until the 13th, when its use was discontinued. On the 17th the progress had been uneventful. The celloidin became loose and was removed with the external sutures on the 15th or the eleventh day. Primary union had taken place except at one point where a small clot had formed between the edges and had thus prevented the line of junction from being uniform. The bowels and bladder had acted regularly. She had been placed on ordinary diet on the 16th. On the 23rd the patient was discharged from the hospital well.

CASE 2. *Ectopic pregnancy; diagnosis before rupture; cœliotomy; removal; recovery.*—A married woman, aged twenty years, was admitted to the hospital on March 3rd, 1898. She was short, dark, and well-developed. She had had one miscarriage eighteen months ago before marriage. She had otherwise been perfectly healthy. She had been married for sixteen months. Her periods, with the above exception, had been regular and normal until two months previously to admission, when she went fourteen days over the proper time. There had been more or less discharge ever since with several shreds and clots. These, however, had been thrown away. She first noticed pain on the left side on Feb. 26th; this came on suddenly whilst she was kneeling as she cleaned the floor. The pain had come in paroxysms ever since. Before entering the hospital the pain was of a bearing-down character, but since lying in bed the character had altered. There was no longer any bearing down, but there was still acute paroxysmal pain and the attacks were becoming more frequent. During the missed fortnight she vomited twice, but she did not vomit after this until the day of admission. She had vomited everything since. She felt as though her left leg dragged upon the parts inside when it was fully extended. There was no pain on defecation but a little sharp pain occurred on micturition.

Bimanual examination showed that the uterus was normal in position and size; the os was perhaps a little softened. A boggy mass of unequal consistence and of about the thickness of a Cambridge sausage, and not unlike it in shape, was close to the uterus, but not fixed to it, and was to be felt in the left fornix; there was some pulsation between it and the finger. Nothing was to be felt in Douglas's pouch. The abdomen was supple, but the skin was dry and harsh. The breathing was costo-abdominal. The pulse was 68, the temperature was 99·4° F., and the respirations were 16. The colour of the lips was good. The face was placid except when the pain returned, when it indicated considerable suffering. A diagnosis of extra-uterine pregnancy, as yet unruptured, was made, and a dose of nepenthe was given. The patient slept for the first part of the night, but the pain woke her up in the early morning and continued with intervals until the operation was performed at 11 A.M. She was wheeled into the theatre, but she got upon the table without assistance.

On March 4th, with the patient in the Trendelenburg position, abdominal section was performed. There was no blood seen under the peritoneum. When this was opened there immediately came into view the left tube which was much enlarged and engorged with blood. About its centre a large rent was seen which was plugged by a firm clot dark red in colour. The abdominal end was closed, curled round and adherent to the ovary. The tube was clamped at both ends, tied and removed. One small adhesion of the tip of the omentum was also tied and divided. In Douglas's pouch, which was unusually deep, some dark clots and fluid blood were found; these and some more dark blood which was found floating amongst the intestines were sponged out. No irrigation was employed. The right ovary was enlarged and cystic and was removed. The right Fallopian tube was enlarged, thickened, and elongated, but otherwise it was healthy; it was left. All raw surfaces, including the stumps, were sewn over by fine catgut, so restoring the continuity of the peritoneum. No drainage was used. The uterus was noted as being slightly enlarged, roughened, and reddened. The abdomen was closed by triple suture and the wound was covered by celloidin.

On returning the patient to bed the temperature was 98·6°, the pulse was 96, and the respirations were 28. There was slight hiccough and she complained of some pain in the back and abdomen, but this had disappeared by the next morning after a hypodermic injection of morphia. Once she passed urine involuntarily, about 3 A.M. on the morning of the 5th, but always naturally afterwards, not requiring the catheter. She vomited once only. A grain of calomel was given every hour for 6 hours. Flatus was passed at 6 P.M. on the second day and the bowels were moved at 10 A.M. on the third, about 48 hours after the operation. In accordance with the usual practice at the Ancoats Hospital nothing was given by the mouth for the first 48 hours, after which feeding was begun with hot milk and beef-tea in small quantities. Nutrient enemata, however, were given after the first 24 hours. There had been no further loss of blood *per vaginam* after the operation until 2 P.M. on the third day, when some slight discharge occurred. This continued and increased until the eighth day, when it decreased and ceased on the ninth. No more shreds or any mass which could be recognised as decidua were seen and that day it was noted that the os

Digitized by Google

was quite closed. At no time was the discharge offensive. The sutures were removed on the ninth day, when primary union of the wound was found to have taken place. The abdomen was supple and undistended. Two days after the operation there was slight tenderness on pressure over the left iliac region. This quickly disappeared and the patient rapidly recovered.

Remarks by Mr. STANMORE BISHOP.—The entire absence of shock or collapse or of any noteworthy pain before the operation, which usually shows that rupture of the tube has occurred and considerable loss of blood has taken place into the general cavity of the abdomen, in both cases, is perhaps worthy of attention. The character of the clots pointed to the occurrence as having taken place within 48 hours before. There was no extra pain or collapse and the patient slept as comfortably as usual on the night before the operation.

YORK COUNTY HOSPITAL.

A CASE OF AMENORRHŒA FOR TWO YEARS; SMALL SOLID TUMOUR IN THE LEFT OVARY; REMOVAL OF TUMOUR; RETURN OF MENSTRUATION; PREGNANCY.

(Under the care of Mr. W. H. JALLAND.)

THE patient, aged twenty-six years, was married, but had never been pregnant. She came under Mr. Jalland's care at the York County Hospital and stated that she had suffered from amenorrhœa for two years, which she considered to be due to over-exertion when she was nursing her mother. She was rather anæmic in appearance, but she had no pain or other symptom. Upon examination a small tumour of about the size of a large hen's egg was detected on the left side of the uterus, being apparently connected with the left ovary. The uterus was small and the sound passed barely 2 in. The os was conical with an almost pin-hole aperture. Removal of the tumour was advised, and the patient consented. The operation was performed in the usual way on Feb. 23rd. The tumour proved to be a small solid one which had no adhesions. The patient made an uninterrupted recovery, which presented no particular points of interest. She began to menstruate in a normal way on March 23rd and continued to do so regularly each month until June when she became pregnant. She called Mr. Jalland to see her in October last year, when he found that she was between four and five months advanced in pregnancy. He saw her again in May of this year, she having been confined of a healthy child two months previously. She had lost all her anæmia and looked the picture of health and happiness.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Treatment of Chronic Bright's Disease.—Rheumatic Dilatation of the Heart.

A MEETING of this society was held on June 28th, the President, Mr. BRYANT, being in the chair.

Dr. EWART read a paper on the Treatment of Chronic Bright's Disease (Tubal Nephritis). He pointed out that the methods of treatment, medicinal and general, hitherto adopted in tubal nephritis had not proved curative of the disease or always of its symptoms. On the other hand, the complete and apparently spontaneous recovery of some cases after long periods of ineffectual treatment showed that the lesions were not necessarily incurable or fatally destructive of the renal structure or function. The cases considered in the paper were strictly those of uncomplicated tubal nephritis with dropsy, a disease which left no permanent lesion behind it and which might be regarded as an inveterate epithelial catarrh. In other varieties of kidney disease this epithelial catarrh was only one of the features; they presented more or less intertubal and Malpighian congestion and cellular proliferation and varying degrees of fibroid proliferation throughout the organ. Their treatment was much less hopeful. In them, as also in the purely tubal nephritis, the albuminuria was a separate factor; and this was not necessarily amenable to the treatment which might prove curative of the dropsy. The group of "acute nephritis" presented great analogy with that of chronic tubal nephritis and the indications were largely the same, but its treatment could only be referred to incidentally. The usual well-known features of tubal nephritis were—(1) the dropsy; (2) the anæmia; (3) the oliguria; and (4) the cachexia and marasmus, disguised by the persistent œdema and paving the way to fatal complications or exhaustion. The treatment described was based upon a consideration of these symptoms and particularly of the œdema. Dropsy might be considered as nature's protection and remedy against fatal intoxication; but also, if not dealt with therapeutically, as nature's difficulty and danger. In itself œdema was harmful when persistent by oppressing the tissues, choking the lymphatic circulation and impeding metabolism. So long as it was present it hindered nutrition both locally and in general. Its usual treatment by horizontal rest in bed further depressed the vital functions. These were the systematic evils of œdema. Another set of results affected the kidney itself, the impeded nutrition of which was rendered more difficult by the absence of a free lymphatic flow. By virtue of this persistent œdema tubal nephritis became a lymphatic disease and its treatment might properly be considered from the point of view of the lymphatic system. The indication was to relieve the lymphatic system of the œdema over as large an area as possible and to ensure its escape by systematic drainage. This was to be effected by posture, since gravitation tells upon renal dropsy, although less than upon cardiac œdema. The œdema should be allowed to collect in the lower limbs by slanting the bed, and meanwhile the trunk and the upper limbs, relieved of their puffiness, can be restored to healthier action by massage. Acupuncture or incision and drainage afforded positive relief to the œdematous tissue of the entire body, to the serous cavities if previously occupied by fluid, and to the lymphatic circulation. They also fulfilled the first indication, that of removing from the body the accumulation of contaminated fluid. Moreover, if persevered in systematically, this treatment satisfied the primary indication of physiological rest to the kidney by opening up another channel of exit for the ingested fluids. The lymphatic system then became to a great extent the channel of emunction. A surcharge of the blood with alimentary and with effete products being largely obviated, a varied and sustaining diet could be prescribed, and on the strength of the latter a larger share of renovating exercise might be allowed than was otherwise possible. It had been shown by Hamilton[1] that the inflammatory products of nephritis were largely removed through the lymphatics of the kidney, a mode of relief analogous to that observed in pneumonia. This observation was in harmony with the *rationale* of the method advocated by Dr. Ewart, and it suggested that a free lymphatic circulation was an essential part of the treatment of the kidney in nephritis. The broad indication which had suggested itself to Dr. Ewart was to place every function in the most normal condition possible in order to assist nature in repairing the local damage. It had seemed to him that the prevailing methods had failed—(1) by not systematically relieving the œdema, but rather promoting its prominence all over the body; (2) by imperfectly carrying out the indication of physiological rest to the kidney; (3) by endeavouring to obtain diuresis by medication and to influence the tissue changes by alteratives at a time when the nutrition of the kidney as well as its function were in abeyance, whilst the treatment by sweating and by purging had often proved an additional trial to the strength; and (4) by neglecting the measures both of hygiene and of diet which were most likely to restore normal strength and nutrition to the system constitutionally and locally to the kidney. The special objects of the treatment proposed were: (1) to unblock the lymphatic ways choked by œdema; (2) to establish a thorough flow from the blood, and particularly from that of the renal district, into the lymphatics, whereby soluble solids and toxic products may be removed; and (3) to quicken artificially the lymphatic circulation by passive movement, general massage, &c., so as to favour nutrition and metabolism of the entire body, and by that means of the kidney also. When the œdema was general or localised elsewhere the first indication is to bring it down to the feet by slanting the bed. Southey's tubes, or small incisions where

[1] Journal of Anatomy and Physiology, vol. xxv., pp. 198–200.

Digitized by Google

these could be made into dilated lymphatics, preferably at the back of the ankle, were the means of draining the œdema. Every antiseptic precaution must precede the operation and must be kept up throughout the case, the part being kept covered by antiseptic dressings, and the entire foot covered with vaseline to prevent soakage of the skin. Large quantities of fluid might be got rid of in this way. In one case the drainage was kept up for two months. Whilst the flow continued a liberal diet could be adopted, the chief aim of the treatment being to raise the patient's strength, but it might be necessary at times to return for a few days to a strictly milk diet. This would help to restore an abundant flow where the latter tended to dry up. A moderate allowance of tonic wine, such as Burgundy, St. Raphäel, or claret, was part of the dietetic treatment. The patient in any recent case would soon be able to sit up and subsequently to walk about the room. Where prolonged illness had preceded the application of treatment active exercise would have to be carefully adjusted to the gradual return of strength. The ordinary rules applied as regards treatment of the liver and of the alimentary canal. One great object of this treatment was to restore cardiac energy and nutrition, which ultimately tended to fail. This object being partly attained drugs could be tried with much better results. Digitalis might then assist both the heart and the kidney. Iron, indicated by the anæmia, would be better borne and such drugs as mercury and arsenic as well as the bitter tonics could be tried with much greater prospect of success. The treatment described was specially devised for cases of dropsy. The advantages to be gained from it were not, however, necessarily restricted to such cases. Uræmia occurring without dropsy was treated by the removal of so much blood. Analogous relief might be secured without the sacrifice entailed by venesection if a sufficient flow of lymph could be obtained by artificially setting up dropsy of one or both lower limbs. Dr. Ewart had succeeded in fulfilling this indication in a case where the œdema was exceedingly slight although affecting the face as well as the lower limbs. The case not presenting urgent symptoms did not justify severe measures; nevertheless, the artificial œdema was kept up for 12 days and the flow obtained through a single incision continued 7 days, although it was never considerable. The local œdema was obtained by the diffused pressure from a tourniquet applied over cotton wool and cardboard to Scarpa's triangle. Martin's bandage was subsequently substituted for the tourniquet. The treatment suggested addressed itself indirectly only to those conditions which kept up albuminuria independently of nephritis and to the restoration of that part of the renal function supposed to be concerned with active internal secretion; and it claimed merely to be an endeavour to assist vicariously the excretory mechanism of the kidney. It was felt, however, that if this indication could be fulfilled the other renal functions would benefit in a large proportion also.—Dr. HOWSHIP DICKINSON demurred to the use of the term large white kidney by Dr. Ewart as synonymous with tubal nephritis. In the large white kidney there was much hypernucleation and increase of the interstitial connective tissue. He thought also that Dr. Ewart undervalued the part played by the tubes of the kidney itself in carrying off the morbid products. Without unduly disparaging the part played by the lymphatics he held that the tubes were the chief channels of excretion, as shown by the abundance of tube casts and epithelial débris seen in the urine, often in sufficient quantity to form a deposit which could be seen by the naked eye. Dr. Ewart claimed that by drawing off the œdema he could relieve the ascites and hydrothorax, but Dr. Dickinson held that although drawing off an ascitic or a pleural effusion might relieve œdema of the legs by taking off pressure from the central veins the converse did not hold. He did not take such an unfavourable view of the prognosis in these cases as Dr. Ewart appeared to do. It was true that in the old days some cases were cut short by too active treatment, but he had found that following familiar lines renal dropsy was very amenable to treatment. Treatment by puncture or incision was a very old one which had been formerly discredited owing to frequent supervention of erysipelas or septic cellulitis. But now, owing to Listerian methods, it could be practised with little risk and Dr. Ewart had done well to bring it prominently forward. But he was not clear how far such drainage would relieve the uræmic condition. It was true that occasionally patients expressed themselves as better when œdema occurred and it was true that there was urea in the dropsical fluid in such cases. But there was also urea in the blood in the same cases and he thought it probable that the urea escaped from the blood by simple filtration just as the other saline constituents did, and were not thrown off as an excretion. Experience had led him always to try to prevent dropsy or to remove it when present, but Dr. Ewart had so high an opinion of it that he proposed to induce it artificially. He did not appear to have been very successful, and, even if he had, the relief to the uræmic process must have been small. Dr. Dickinson thought that in all cases of renal dropsy there was a tendency, which varied in different cases, to spontaneous recovery which might not show itself for a long time. He thought that this recovery was contemporary with the occurrence of hypertrophy of the left ventricle.—Dr. NORMAN MOORE asked for details of the number of cases observed and the course of the symptoms. Dr. Ewart had drawn attention to the importance of keeping up the action of the heart under treatment, a point insisted on by Southey. It was rare to examine cases of renal disease (other than acute ones) post mortem without finding degenerative processes in the heart wall. There was no doubt a great difference in the clinical type as presented by the two sexes. A woman had about three times as long an expectation of life as a man similarly affected, possibly owing to the different ways of life. He thought that much active exercise was dangerous and that a man's life when convalescent should approximate to that of a woman engaged in ordinary domestic duties.—Sir DYCE DUCKWORTH agreed with Dr. Dickinson in his remarks as to the pathology and as to the importance of the personal element in these cases. In his experience the prognosis was particularly bad in the case of persons of a strumous habit. He took a less gloomy view of the prognosis than Dr. Ewart and relied chiefly on warmth, diuretics, and tonics, and did not restrict his patients to a milk diet. Free incisions with antiseptic precautions often gave great relief.—Dr. EWART, in reply, said that with regard to the possibility of relieving the ascites by drainage of the œdema of the legs he could only say that in the case which formed the text of his paper the ascites had been previously tapped without relief to the symptoms, but that after the œdema had been relieved by incision the ascites rapidly disappeared and on the second day the patient's urinary secretion rose and no doubt helped to carry off the fluid. In another case 150 oz. were removed by incision and in 48 hours the ascites had nearly gone. As regards the use of the term "large white kidney" he admitted that in the class of cases to which he had referred there was intertubal proliferation, but he thought that it was possible to arrest this before it passed on to the formation of fibrous tissue. He did not see how ventricular hypertrophy, being associated with fibrosis of the kidney, would leave the patient any better off, and he regarded the hypertrophy itself as a very undesirable possession. The removal of the dropsy was only a preliminary to feeding up and endeavouring to improve the general condition of the patient, which could not be done while every cell in the body was sodden by the œdema. Although he had only had two cases he thought that the results were so encouraging that he ought to bring them before the society.

Dr. D. B. LEES read a paper on Acute Dilatation of the Heart in Rheumatic Fever. In this paper attention was drawn to the fact that an acute dilatation of the heart was a common occurrence in a rheumatic attack, even when arthritis and pyrexia were slight in amount, and apart from distinct endocarditis and from pericarditis; also that an acute dilatation might, in a more severe attack, intensify the signs and symptoms of pericarditis or endocarditis. The evidence adduced in support of these propositions consisted of tracings of the cardiac dulness at different stages of a rheumatic attack taken by Dr. Lees from patients under his care at St. Mary's Hospital. The question was first discussed whether it was possible by percussion to obtain an accurate knowledge of the actual size of the heart. Reference was made to the writings of Dr. Ewart and to the post-mortem investigations of Dr. Herringham in support of the contention that a tracing representing the outline obtained by careful percussion did indicate with very considerable accuracy the position of the limits of the heart, both to the left and to the right. Tracings taken from the cases showing the size of the cardiac dulness at different periods were thrown on the screen by a lantern. The first three sets of tracings were taken from young adults suffering from subacute rheumatism, with slight

Digitized by Google

arthritis and little pyrexia, with no evidence of pericarditis or distinct endocarditis. Three tracings of the cardiac dulness were shown from each of the cases, the first taken before commencing treatment, the second at an intermediate stage, and the third taken on recovery. They all showed the same events—a large extension of the dulness at first, with gradual reduction and final return to the normal. Next followed a set of tracings showing acute dilatation caused by a subacute attack in a heart already diseased by two previous attacks. The large extension of the cardiac dulness registered in the first diagram was seen to subside until it reached a permanent amount due to the previous disease. Lastly, a pair of tracings were shown from a case of rheumatic pericarditis with chorea, showing how acute dilatation may intensify the signs of pericarditis and how a rapid diminution in the area of the præcordial dulness may occur under treatment. It was claimed that these tracings, though doubtless open to criticism in details, were sufficient to prove that acute dilatation of the heart was a feature of rheumatism which deserved more attention than it had hitherto received. Reference was made to remarks on "swollen heart," by Dr. Sansom; also to specimens of dilated heart after rheumatism exhibited at the Pathological Society by Dr. Goodhart and Dr. West; also to Dr. Goodhart's paper on Acute Dilatation of the Heart after Scarlet Fever, and to a case of the same kind reported by Dr. Barlow. It was suggested that the acute cardiac dilatation produced by rheumatism was analogous to the acute dilatation often resulting from influenza, and that in both cases it was due to the poisonous action of a microbic toxin on the cardiac muscle, similar to the effect of dilute solutions of lactic acid and of certain drugs in causing cardiac dilatation, demonstrated many years ago by Dr. Gaskell.

Dr. D. B. LEES and Dr. F. J. POYNTON read a paper on Rheumatic Dilatation of the Heart in the Rheumatism and Chorea of Childhood. This paper recorded the results of a joint investigation of the subject of acute dilatation of the heart in the rheumatism and chorea of childhood carried out at the Hospital for Sick Children, Great Ormond-street, and results of certain inquiries conducted by Dr. Poynton in further elucidation of the subject. These include (1) observations on the hearts of children under the care of various physicians; (2) observations on the hearts of children free from rheumatism; and (3) an analysis of the post-mortem records of 150 cases of fatal rheumatic heart disease in children under twelve years of age. The paper commenced with statements as to the size, strength, and sounds of the heart in children free from rheumatism mainly deduced from Dr. Poynton's examination of the hearts of 45 patients in the surgical wards of the Hospital for Sick Children and of 35 healthy boys of twelve and thirteen years of age at Marlborough School. The observations on the hearts of rheumatic and choreic children were arranged in four groups: (1) cases of subacute rheumatism with no pericarditis and with no murmur or only a systolic murmur best heard internal to the nipple; (2) first attacks of chorea without any previous history of rheumatism and in the great majority of cases no present evidence of rheumatism except the chorea; (3) acute cases in which there were definite cardiac lesions, pericarditis, or undoubted endocarditis; and (4) cases of chronic and relapsing rheumatism. Tracings were given showing the size of the heart in two or three cases from each of these groups at different stages of the disease. They all showed a considerable increase at first in the area of cardiac dulness, which tended to diminish as improvement set in and which might again increase if a relapse of the disease occurred. During the periods of increase the cardiac impulse became diffused and displaced to the left; when the dulness diminished the impulse became stronger, more localised, and more normal in situation. The heart sounds also were altered when the area was increased, the first sound becoming weak and short, while the pulmonary second sound was accentuated. The sounds became more normal as the area diminished. From an analysis of the post-mortem records of 150 cases of fatal rheumatic heart disease in children under twelve years of age it was shown that dilatation was usually found. In 92 cases out of 150 (61 per cent.) special attention was called to its existence in the records. On the other hand, marked excess of pericardial fluid was rare; in only 12 cases of the 150 was more than 2 oz. noted. The value of acute cardiac dilatation as an aid in the diagnosis of arthritis of doubtful nature was pointed out. Dr. Lees and Dr. Poynton held that in many cases the effects attributed to valvular disease or to adherent pericardium might be mainly due to this dilatation, which tended to increase with each recurrence of rheumatism.—Dr. T. J. MACLAGAN observed that the tendency to cardiac complication diminished as life advanced, being much more frequent between the ages of fifteen and thirty years than afterwards, and in the anomalous cases in children attended by the presence of subcutaneous nodules serious heart mischief was almost constant. He thought that hitherto the myocardium had not received its due share of attention. It was notorious that rheumatism had a special effect on red muscle throughout the body as shown by the rapid softening and atrophy and by the excess of lactic acid present, and there was no reason why the cardiac muscle should escape. He himself would be inclined to hold that there was actual myocarditis. When a murmur was first heard it was usually presystolic and indicated an affection of the ring rather than of the flaps of the valve.—Dr. EWART congratulated Dr. Lees and Dr. Poynton on the way in which their research had been made. Since his attention had been drawn to these cases he had examined all that had come before him, but he was inclined to think that in many cases the increased dulness was due to pericardial effusion rather than to dilatation, and in support of this view he showed a number of diagrams.—Dr. NORMAN MOORE was inclined to share Dr. Ewart's doubts and asked what pathological evidence there was. The only cases he had met with which showed so much dilatation after death as had been described were cases of severe whooping-cough. He looked on endocarditis, not as a complication, but as the commencement of rheumatism, and held that the endocardium was affected in every case of true rheumatism.—Dr. THEODORE FISHER said that in cases of acute pericarditis which proved fatal early it was clear that the superficial inflammation could not be the cause of bringing the heart to a standstill and he believed, with Dr. Lees, that it was a toxin acting on the muscle. He quoted recent observations he had made on cases of fatal pericarditis in which extensive degenerative changes in the myocardium were found without any endocarditis.—Dr. LEES, in reply, said that the gradual reduction of the dulness as the rheumatic attack subsided and its immediate increase when there was relapse were consistent with dilatation rather than with effusion and this was entirely confirmed by the post-mortem records of over 150 cases. In only 12 was there any large effusion, while in no fewer than 92 there was dilatation, often extreme. On percussion there was no triangular patch of dulness near the right nipple such as Dr. Ewart held to be characteristic of pericardial effusion.

EDINBURGH OBSTETRICAL SOCIETY.

Exhibition of Specimens.—Analogues of the Male and Female Genital Tract.—The Position of the Promontory.

A MEETING of this society was held on June 22nd. Dr. MILNE MURRAY, vice-president, occupied the chair.

The following were elected by ballot as honorary Fellows of the Society: Dr. Charles J. Cullingworth, London; Dr. Lombe Atthill, Dublin; Professor S. Pozzi, Paris; Dr. G. Leopold, Dresden; Professor Howard A. Kelly, Baltimore; Professor Henry C. Coe, New York; and Dr. E. Doyen, Paris.

Professor SIMPSON showed specimens of Ovarian Tumours and Doyen's Forceps for Compressing the Pedicle in Ovariotomy.

Dr. BREWIS showed a Cyst with a twisted pedicle and a Large Ovarian Tumour weighing 40 lb.

Dr. FOULIS exhibited Dissections of Embryo Deer to Demonstrate the Development of the Sexual Organs.

Dr. BERRY HART read a paper on the Analogues of the Male and Female Genital Tract. He demonstrated that the sinus pocularis was the analogue of the hymen and lower third of the vagina and therefore that all below and including the sinus pocularis was equivalent to the lower third of the vagina and the vestibule. He had found traces of the uterus masculinus in the prostate of a four and a half months' male fœtus. He regarded the vagina as probably derived from the pronephros and the ovary and testis as certainly developed in connexion with the mesonephros. Thus the sexual glands and ducts were intimately correlated with

Digitized by Google

the Wolffian structure. The various analogues of the organs and the significance of the rudimentary organs in either sex were then considered and a limelight demonstration of specimens was given.—Dr. FOULIS, Professor SIMPSON, and Dr. MILNE MURRAY took part in the discussion on the paper and Dr. HART replied.

Dr. FREELAND BARBOUR gave the abstract of a paper on the Position of the Promontory as shown by Frozen Sections and its Effect on the Build of the Pelvis. Dr. Barbour while teaching students clinically found that there was very great difference in the height of the promontory of the sacrum above the symphysis. In order to determine this point accurately he made measurements of the pelves in 18 frozen sections. The anatomical conjugate was found to vary from 3·80 in. to 5·6 in. The obstetrical conjugate or the distance between the promontory and the nearest point of the symphysis varied from 3·44 in. to 5·28 in. This showed the available conjugate for obstetrical purposes. The difference between the anatomical and obstetrical conjugates varied from ¼ in. to ⅝ in. In order to ascertain accurately the height of the promontory above the pubes a line is drawn from the upper part of the symphysis horizontally backwards; another line is carried from the promontory of the sacrum perpendicularly downwards till it meets the horizontal arc. The measurement of the perpendicular gives the accurate height of the promontory above the symphysis. There is great variability, the promontory standing as high as 5 in. and as low as 2·4 in. above the pubes, the average being 3·7 in. If the horizontal line is carried backwards till it impinges on the posterior wall of the cavity it is found in 12 out of 16 available sections to strike the second coccygeal vertebra or a point below it. From this it is learned that the whole sacrum and a portion of the coccyx is above the level of the upper margin of the symphysis. Another item of interest is the angle formed at the symphysis by the meeting of the anatomical conjugate and the horizontal line. This angle varies from 33° to 65° and gives what Dr. Barbour calls the "set of the brim." He also gave measurements of the horizontal distance of the promontory backwards from the symphysis. These varied from 2·0 in. to 4·0 in., with an average of 2·64 in.—Dr. MILNE MURRAY and Dr. BERRY HART discussed the paper and Dr. BARBOUR replied.

Reviews and Notices of Books.

Diseases of the Nervous System (Lewis's Practical Series). By CHARLES E. BEEVOR, M.D., F.R.C.P. Lond. London: H. K. Lewis. 1898. Pp. xvi. and 432. Price 10*s.* 6*d.*

THIS handbook consists in all of twenty-nine chapters. The first four are preliminary in their character, dealing with the anatomy and physiology of the nervous system in a succinct and lucid but necessarily somewhat sketchy manner and with the methods of examination which should be followed in investigating cases of nervous disease. The rest of the book is devoted, section by section, to a short account of the various diseases of the nerves, spinal cord, and brain, and when it is stated that this account is given in 330 octavo pages it will be recognised that the description of each disease is necessarily short. But everything is very clearly put and for the senior student or busy practitioner the book will, we believe, be found extremely useful. Some of the chapters are particularly good, notably those in which organic brain disease is discussed. We think the author has been wise in leaving rather severely alone the new conceptions of nervous disease which the theory of the neuron necessarily introduces. It is more than likely that our ideas of nervous disease will have to be made to fit in with recent anatomical discoveries, but these are as yet too recent to be dealt with satisfactorily in such a handbook as this.

Several minor points may be noticed, not merely for the purpose of finding fault, but with the view of indicating the possibility of the existence of differences of opinion. In regard to tabes, for example, it is stated that syphilis occurs in from one-half to two-thirds of the cases as a predisposing cause. If we are not mistaken Erb in his most recent series of cases found that the proportion was much higher—as much as 90 per cent., we believe. Then, again, pseudo-hypertrophic paralysis and idiopathic muscular atrophy are described as different diseases. No doubt it is true that typical cases are distinct enough, but according to the most recent teaching on the subject these varieties are most likely the different ends of a long series with intermediate examples of varied combinations of the two conditions. And we venture to doubt whether in reference to the surgical treatment of epilepsy it is quite justifiable even in cases where the character of the fit clearly denotes a localised disorder to remove the piece of the cortex corresponding to the part in which the fits commence. These, however, are all points on which an author is entitled to his opinion, especially if the opinion is backed, as in this case, by wide experience and accurate observation. In a small work it would, of course, be unreasonable to expect anything more than the expression of an opinion. We cannot expect to have also the data on which the opinion is based. It is a pity, we think, that an account from the neurological aspect has not been given of general paralysis. Nearly all the descriptions of this disease are given in handbooks of mental disease and naturally from the mental aspect. It is now well known, however, that there are many cases of general paralysis in which the mental symptoms are subordinate to the physical. These are cases which come before the neurologist and a description of them from the neurological standpoint would have formed a valuable addition. On the whole, however, the author is to be congratulated on a work which is clear and, considering its size, wonderfully complete, and the publisher on a most useful addition to an eminently useful series.

Vade Mecum of Ophthalmological Therapeutics. By Dr. E. LANDOLT of Paris and Dr. P. GYGAX of Milwaukee. Translated by Dr. E. NEYMAN of Milwaukee. London: J. B. Lippincott Company. 1898. Pp. 138. Price 3*s.* 6*d.*

THE purchasers of this small volume will find arranged in alphabetical order the names of the chief diseases of the eye intercalated with which is a list of the various drugs and methods of treatment which have been employed for their relief; cross references are in many instances given and the appropriate dose of each drug is appended. Perhaps an example will best show the plan adopted and we select iritis. "Iritis, plastic, rheumatic, arthritic, blennorrhœic, syphilitic. *Mydriatics:* Atropine (23 a), alternating with duboisine (102) or combined with cocaine (23 b) or a combination of atropine, cocaine, and duboisine (23 c). Should the pupil not be enlarged by these solutions: Extract of belladonna or duboisine in substance (having care to close lachrymal points by pressure). Close the eyes for at least five minutes after instillation. Always watch the intraocular tension; as soon as tonus is + replace the mydriatics mentioned by scopolamine (284). *Rest for the Eyes.*—Bandage the eye affected; dark room or smoked glasses according to cause and intensity of disease. *Avoid* sudden changes of temperature, draughts, &c. Blood-letting or dry leeches at temple. Iodine ointment (146 b). *Poultices* (255), hot compresses. For severe pain hypodermic injections of morphia (231 c). Laxatives, diuresis, and diaphoresis (305). Etiologic treatment: Where there are other symptoms of *rheumatism* salicylate of soda (275), antipyrin (15), antifebrin (14), alkalies, acetate of potassium (254), lithia water (225 b). Turkish baths. In case of urethral blennorrhœa, salol (278) and energetic treatment of the urethral trouble. In *syphilis*, specific treatment (291).

Digitized by Google

For dysmenorrhœa, scrofula and anæmia, strengthening treatment arsenic (20), iron (164), &c. *Continue mydriatics for some time* after inflammatory symptoms have disappeared. Should synechiæ capable of bringing on relapses remain iridectomy may be indicated." The numbers in parentheses refer to the corresponding headings in which the action and dose of the drug are given. It will be seen that there is little to be added to the above list of remedies which are employed in reducing iritis and that the work fully answers to its title. It will certainly prove very serviceable to those who are able to make a fairly good diagnosis of the nature of ophthalmic diseases, supplying them, as it does, with a concise pharmacopœia.

A Manual of General Pathology. By W. S. LAZARUS-BARLOW, M.D. Cantab., late Demonstrator of Pathology in the University of Cambridge. London: J. & A. Churchill. 1898. Pp. xi. and 795. Price 21*s*.

DR. LAZARUS-BARLOW has attempted a bold task and his attempt has met with no small amount of success. No original book dealing comprehensively with experimental pathology has previously been produced in the English language and the need for such a work was conspicuous. Cohnheim's "Lectures on General Pathology," translated by the New Sydenham Society, form, as they will no doubt continue to form for some time to come, the classic on the subject, and quite recently a portion of Thoma's valuable work has become available in English. But the translation of Cohnheim's work dates from 1882 and a more modern work is now necessary for students; while Thoma is so original in his treatment of some branches of the subject that he can hardly be considered to represent ordinary modern teaching in general pathology. Both the above-named works are, moreover, very bulky. This, then, is the gap which Dr. Lazarus-Barlow has endeavoured to fill and he has produced a manual which will be of very great value to the student. It is not fair to compare it with Cohnheim's book. Cohnheim was a pioneer in an almost unworked field and our modern teaching took its rise in his labours; his lectures remain as a monument to his originality and genius. At the present time a writer on general pathology must draw largely on the results of others, and a good student's manual must be mainly a judicious compilation, well balanced and critically edited. This work has been accomplished by the author in a very excellent manner, and the English student has now at his command a good and lucid summary of the main facts of experimental pathology presented within the reasonable compass of some 800 pages. The writer has, as he frankly admits, drawn freely upon Cohnheim's writings, and he has laid under contribution most of the important original work which has appeared in more recent times; in particular he admits his indebtedness to the various writers who have contributed to Clifford Allbutt's "System of Medicine." All parts of the book are naturally not equally good and it is not difficult to find fault here and there with individual statements. Thus on p. 63 both the anatomist and the practical physician will be surprised to read that "lesions of the tricuspid valve rarely produce any specific murmurs, partly by reason of the depth at which the valve is situated in the thorax and partly," &c., &c. The murmur of tricuspid regurgitation is a common one and the valve is more superficial than the mitral. Most bacteriologists will also learn with astonishment that staphylococcus pyogenes aureus is commonly present in the vegetations of simple endocarditis. It is not even the commonest organism in infective endocarditis. The pathology of the heart is, however, very well put from its physiological side and is soundly based upon experimental work. The author's own work on œdema is well known, and if he has treated this branch of the subject at somewhat undue length he may well stand excused on account of its interest and importance. This is perhaps one of the best sections in the book. The chapters on inflammation are full and clear and the chief objection to the author's concluding definition of that process is one which is common to all attempted definitions of inflammation—that it would convey to one ignorant of the subject no idea whatever of what inflammation is really like. The pathology of infection again is very well treated and there is a good criticism on the phagocyte theory of immunity. The pathology of fever is also excellently set forth. Space fails us to criticise in detail all the sections of the book, though certain omissions may be noticed. Thus under the theories of uræmia, we fail to find any reference to Bouchard's views, which, whatever opinion may be held as to their value, certainly merit discussion. No reference, again, is made to Cabot's book in the literature of blood diseases. It would, however, be unjust to insist upon such matters as these in face of the very signal service which Dr. Lazarus-Barlow has rendered in the production of this manual. He has done his work laboriously and conscientiously and has for the first time provided the student of pathology with a compendious and lucid exposition of the subject of experimental pathology—a subject which must more and more be recognised as lying at the very root of rational medical and surgical education.

LIBRARY TABLE.

A Practical Treatise on Sexual Disorders of the Male and Female. By ROBERT W. TAYLOR, A.M., M.D., Clinical Professor of Venereal Disease at the College of Physicians and Surgeons (Columbia College), New York; Surgeon to Bellevue Hospital, &c. With 73 Illustrations and 8 Plates in colour and monotone. London: Henry Kimpton. 1897. Pp. 451. Price 12*s*. net.—The branch of surgery with which this work deals is one about which very little is said in most text-books of surgery and yet its importance is by no means small, for whether we consider the frequency with which such cases present themselves or the amount of unhappiness which results from them it is very obvious that they are worthy of the most careful attention of the surgeon. Dr. Taylor deals in the first place with the anatomy and physiology of the male sexual apparatus and it is interesting to note that he is inclined to accept the results of the researches of Professor George S. Huntingdon, who asserts that the vesiculæ seminales never contain semen and that they do not act as places of storage of this fluid, but they provide a special form of mucus to dilute and carry on the semen. Impotence and sterility in the male are thoroughly considered and a chapter is devoted to the mental effects of sexual disorders. With regard to sterility in the male, the author thinks that probably in one case in six of unfruitful marriages this is the cause. The second half of the book deals with sexual disorders in the female. The final chapter treats of a peculiar new growth of the vulva, three examples of which Dr. Taylor has seen. He has already written on this condition in the *American Journal of the Medical Sciences*. In some respects it resembled a tertiary syphilitic condition, but potassium iodide seemed to have no effect upon it, and microscopically it appeared to be inflammatory. The volume is a trustworthy treatise on a difficult subject.

Transactions of the American Climatological Association for the Year 1896. Vol. XII. Containing Part II. of the Report of the Committee on Health Resorts. Philadelphia: Printed for the Association. 8vo. Pp. 293.—The American Climatological Association has not only for its object the study of climatology but also of hydro-therapeutics,

Digitized by Google

and of the diseases of the respiratory and circulatory organs, and hence we find in this volume of its transactions papers on a few subjects that have but little to do with climatology. However, the greater number of the papers are concerned with the influence of climate on disease and they are well deserving of being printed. Perhaps the articles of most interest to medical men on this side of the Atlantic are those which deal with the climatic conditions of particular health resorts, and we may specially mention a paper on the Climate of Arizona. A valuable appendix contains the second instalment of a report of the committee upon health resorts; in it are given brief accounts of 50 such resorts, with analyses of the waters, if they possess medicinal springs.

International Clinics: A Quarterly of Clinical Lectures and Specially Prepared Articles on Treatment by Professors and Lecturers in the Leading Medical Colleges of the United States, Great Britain, Germany, Austria, France, and Canada. Edited by JUDSON DALAND, M.D. Philadelphia, Instructor in Clinical Medicine and Lecturer on Physical Diagnosis in the University of Pennsylvania, &c.; J. MITCHELL BRUCE, M.D., F.R.C.P. Lond., Physician to, and Lecturer on Medicine at, Charing-cross Hospital; and DAVID W. FINLAY, M.D. Glasg., F.R.C.P. Lond., Professor of Practice of Medicine in the University of Aberdeen, &c. 1896-97 Series. London: Lewin and Co. Vol. i., pp. 344; vol. ii., pp. 359; vol. iii., pp. 349.—The value of clinical lectures is becoming more fully recognised, for they form a very useful adjunct to the accounts of diseases given in text-books. The form of the clinical lecture should differ greatly from that of a lecture in a systematic course of medicine or surgery, but, unfortunately, this difference is not always recognised. These volumes form a portion of a most useful publication appearing quarterly. Each number contains more than forty clinical lectures, which have been delivered by recognised authorities in the subjects to which they refer. The majority of the authors are American, but many are British, and not a few are French, German, and Swiss. By the sub-title of the work it will be seen that all departments of medicine and surgery are dealt with, and though the lectures are necessarily of unequal merit, yet we cannot say that there is one which does not deserve a place in the volumes. Plates and diagrams, though not numerous, exist in sufficient quantity to illustrate the lectures satisfactorily.

Die Behandlung der Syphilis nach den gegenwärtig üblichen Methoden. Für die ärztliche Praxis. Dargestellt von Dr. F. GRIMM, in Berlin. (*The Treatment of Syphilis by Modern Methods.* By Dr. F. GRIMM of Berlin.) Berlin: S. Karger. 1896. Pp. 103. Price 2*s.* 6*d.* net.—This work gives a fairly complete account of the various methods of treatment of syphilis which are in use at the present day. It is specially concerned with the treatment of the primary and secondary manifestations of the disease and the treatment of tertiary syphilis is considered rather more briefly. We think that the treatment of the congenital form of the disease might with advantage have been fuller. As might have been expected a large amount of space is devoted to the hypodermic method of the introduction of mercury into the system. Dr. Grimm points out that there are two hypodermic methods which differ in an important point: in one insoluble preparations are injected and in the other soluble salts of mercury are employed. The injection of insoluble preparations of mercury was introduced by Scarenzio in 1864, but it has almost entirely given place to the injection of soluble salts, if the hypodermic method is employed at all. A very brief account is given of the "blood-serum" treatment of syphilis and it cannot be said in the present stage of our knowledge of the subject that it deserves much consideration.

Stretcher Drill, Illustrated, including Hand, Seat, and Wagon Drill. By Surgeon-Major J. J. DE ZOUCHE MARSHALL, Hon. Assoc. of St. John of Jerusalem in England, Army Medical Reserve of Officers, 3rd V. R. East Surrey Regiment, &c. London: William Clowes and Sons, Limited. 1898.—The simple announcement of the title of this little book, which is published by permission of Her Majesty's Stationery Office, is sufficiently explanatory of its nature and object. It is well illustrated and the accompanying letterpress descriptions and directions are clearly and well given. The book should prove useful as a practical guide to volunteer surgeons and others and especially to such as are desirous of instructing regimental ambulance classes in stretcher drill as well as in First Aid. The best and indeed the only sure way of learning any drill, however, is, as pointed out by the author, to go through it in the ranks under a competent instructor.

Elementary Chemistry, Practical and Theoretical (First Year's Course). By T. A. CHEETHAM, F.C.S. London: Blackie and Sons. 1898. Price 1*s.* 6*d.*—This book is the companion of "Elementary Physics, Practical and Theoretical," which was reviewed in THE LANCET of June 25th, 1898. The author suggests a perfectly correct though somewhat laboured method of recording the weight of a substance; the treatment is otherwise very definite and concise.

Pocket Notes on the New British Pharmacopœia, 1898. Bristol: Ferris and Company. Pp. 123.—The alterations in strength, composition, or dose which the new Pharmacopœia requires to be substituted for those contained in its predecessor occupy about ninety pages of this little book. On an average there are about five formulæ on a page, extra space being allotted to the tinctura chloroformi et morphinæ composita, which differs very materially from the old tinctura chloroformi et morphinæ. The additions, omissions, and alterations in nomenclature, all of which are clearly shown, make up the rest of the book. As its name denotes it is of a shape and size convenient for the pocket.

The British Pharmacopœia, 1898: Alterations, Additions, and Omissions. Sixth edition. London: *Pharmaceutical Journal* Office. Pp. 48. Price 4*d.*—This pamphlet, which is a reprint from the *Pharmaceutical Journal*, gives the essential particulars relative to the preparations the names, composition, strengths, or doses of which have been altered in the new Pharmacopœia. Its arrangement is alphabetical, beginning with Acetum cantharidis and ending with Vinum Xericum, whereby prescribers will have no difficulty in finding the references which they may happen to require. In the case of several of the new extracts, as well as of tincture of opium, the processes of preparation and of standardising with a view to obtaining a finished product of definite chemical strength are described with much fulness. At the end there is a useful table showing the proportions in which spiritus rectificatus must be added to water in order that the mixture may contain a given percentage of absolute alcohol.

Pocket Guide to the British Pharmacopœia, 1898. By FRESHFIELD REYNOLDS.—In this concise summary, published by the author, a pharmaceutical chemist of Harrogate, the changes in the new Pharmacopœia which more particularly concern the prescriber are brought into the convenient compass of eight pages. Special attention is therefore directed to articles which have undergone important alterations of strength, such as the extract of Calabar bean, infusion of ergot, blistering fluid, together with several of the "spiritus" and tinctures. Practitioners will find these notes very easy for reference on account of the absence of details which are of merely pharmaceutical interest. A copy will be sent to any member of the medical profession on receipt of name and address and 1*d.* postage stamp.

THE LANCET.

LONDON: SATURDAY, JULY 2, 1898.

ON Tuesday night the House of Commons proceeded with the consideration of the Prisons Bill as amended by the Standing Committee. After discussions upon flogging and the treatment of treason-felony prisoners the House passed to the consideration of a subject certainly of deep interest to the whole country and one with which we are immediately concerned. The Home Secretary moved to omit from Clause 1 of the Bill the words "and one of them [i.e., the Prison Commissioners] shall be a medical man skilled in mental diseases." These words had been inserted by the Grand Committee but he did not think that the hands of the Secretary of State ought to be tied by having the appointment of a medical officer skilled in mental diseases made compulsory, though he desired to strengthen the medical element among the Commissioners. In the discussion which followed the Irish Members and many Radicals spoke against the Government, while the front Opposition bench eventually voted with them. A compromise was arrived at, the Home Secretary promising to insert a minute on the records of his office to the effect that it was desirable to appoint a medical Commissioner as well as medical inspectors. It is allowed on all hands that insanity is prevalent in prisons and in all probability the prison routine of the past has had a great deal to do with bringing this about. We cannot agree with those who submit that all crime is insanity, other than in the sense that it is a deviation from the normal. But the ordinary criminally minded man or woman is certainly of very low mental calibre and is mentally unstable, and this being so it is of the greatest consequence that among those appointed to supervise his, or her, treatment and punishment there should be some who have made a study of mental affections.

The present Prisons Bill has made one great step in the matter of prison reform, for as at present drafted it hands over the control of prisons to the House of Commons. But the Prison Commissioners will, we take it, be allowed a certain amount of latitude. Upon them will fall the duty of seeing that the decisions of the House with regard to various matters connected with prison discipline are carried out as they should be. For this purpose medical knowledge will be most valuable and we utterly fail to see the force of the objection of the Home Secretary to the words which he proposed to omit and which have been omitted by a majority of 97. These words were inserted by the Grand Committee and the Standing Committee on Law voted for their insertion by 25 votes to 8. We are far from agreeing with those Members who implied that the decisions of a Committee of the House of Commons should necessarily bind the House itself, but on a matter such as this, where it was allowed by the responsible Minister that increased medical representation was very desirable, it seems to us that th words in question might very well have been allowed to stand part of the clause. One speaker suggested that it was not due to the action of the Home Secretary but to the permanent officials of the Home Office—a view, however, dissented from by Sir MATTHEW WHITE RIDLEY, who took all the blame upon himself. We cannot acquiesce in the charge of unfairness which was brought against him by one Member. The Home Secretary fought the addition to the clause—i.e., the words now omitted—in the Grand Committee, was beaten there, and had every right to fight it again in the House. But in the wisdom or policy of this action we cannot agree. The appointment of a medical Commissioner is not one merely of expediency but of necessity, and, though the compromise arrived at is better than nothing, yet the omission of the words in dispute is a serious blot upon the Bill.

The whole debate was an excellent example of the curious affection which the House of Commons has for hair-splitting, a fact duly noted and commented upon by Mr. BALFOUR. Another point brought out is the dislike that this Government, and we might say every Government, has to saying "must." To our minds the very essence of Government is to say "must." Permissive Bills are never of any use. The Home Secretary argued that he did not want either his hands or those of his successor tied. But the whole object of a law is to tie someone's hands. Sir MATTHEW WHITE RIDLEY allows that a strengthening of the medical element is desirable and yet he omits the very clause in the Bill which provides for this reform. However, as he has pledged himself to place on record at the Home Office a minute to the effect that the medical element shall be represented among the Commissioners, a minute which, though not binding on future Home Secretaries, shall yet, in the words of Mr. ASQUITH, be a guide for them, it is possible that not much, if any, harm has been done.

IN THE LANCET of June 18th we called attention to the subject of the hospital equipment and the medical and sick transport arrangements provided for the troops at the battle of the Atbara, about which a series of questions had been recently put to the Under Secretary for War in the House of Commons. Mr. BRODRICK admitted, it will be remembered, that the litters used for the wounded were not provided with sun protectors in the shape of folding hoods and that no Roentgen ray apparatus had accompanied the field force, adding, however, that measures either had already been, or would be, taken to supply the deficiencies in both these respects. He pointed out at the same time the difficulties attending the adaptation of the Roentgen apparatus to field service and declared, on the authority of the senior medical officer, who had gone very carefully over the cases, that no instance had as a matter of fact occurred in which the apparatus would have been specially useful or would have been instrumental in saving a single life. As regards the other subjects of complaint the Under Secretary for War either refused to allow that there were any grounds for their existence or minimised their importance. He saw no reason for the appointment of any Parliamentary or other committee of inquiry. We said that although Mr. BRODRICK'S replies were on the whole satisfactory we should have been glad if he had expressed himself more definitely in respect of

Digitized by Google

the allegations which had been made regarding the severely economical scale on which our Egyptian campaigns had been hitherto conducted. We added that while quite ready to admit that it was not always possible to provide for every contingency occurring on field service, whatever was practicable should unquestionably be done, and that if for financial or military reasons this was not done the responsibility should not be allowed to rest with the medical branch of the service.

Judging from what has since been published Mr. BRODRICK'S explanatory statements in the House of Commons do not seem to be regarded as adequate and we consequently feel amply justified in the comments we made on the occasion in question. Nothing could have been better than the way in which the medical officers did their work at and after the battle of the Atbara, and we have been assured that there was, as a matter of fact, plenty of chloroform at the front. But even were it otherwise, we may safely assume that whatever shortcomings there might have been in respect of anæsthetics or of any other hospital stores they would have been attributable to the self-same cause which is continually *en évidence* in our campaigns—want of transport. The provision of sufficient transport means, of course, the expenditure of money and we may be pretty confident that if any branch of the service is to be squeezed in this respect it will not be the military but the medical branch of the service. We do not say, of course, that such was the case, but if stores and equipment required at the Atbara were at Wady Halfa, for example, they might as well have been at Cairo or in England. Instead of the necessary amount of transport being handed over to the medical department for its special use, to be disposed of in the best way to meet its requirements in the field, medical officers have never, so far as we can learn, had a free hand in this respect in any campaign which has yet taken place. Supposing the required amount of stores and equipment to be allowed and not cut down, there is nevertheless no assurance, as it seems to us, under the present system that they will be forthcoming at the times and places where they are most needed. The military operations in the Soudan against the KHALIFA have been for the benefit of civilisation and humanity; they have been designed and carried out with great skill and at a relatively small cost. The question is, however, whether this policy of cheapness has not been carried too far. The demands on a medical service in the field are becoming more and more severe and exacting, and the force of public opinion in this direction will increase rather than decrease as time goes on. In the coming expedition of the Anglo-Egyptian army to Khartoum the finance and military authorities must be prepared to meet the requirements of the medical service or in common fairness to that service to publicly accept the full responsibility of the position.

IN a recent article[1] we held that it was our duty as a profession to tell the State how it may prevent and control small-pox, but that it was the duty of the State itself to decide how the prophylaxis shall be applied. Every individual in the realm should be vaccinated and re-vaccinated and the State should use all reasonable legislative pressure towards this end, but we argued that the question of how far compulsion should be resorted to is one in which medical men are interested rather as units in the body politic than as a profession. By the narrow majority of 2 votes (26 to 24) the Grand Committee on Law has rejected Sir WALTER FOSTER'S amendment in favour of a conscience clause as regards primary vaccination. So far as the Committee is concerned the State has therefore decided that pressure to a certain extent — afterwards modified — may be exercised towards the vaccination of every child. Our views on this question have been sufficiently expressed since fresh legislation began to be talked of and we need not repeat them here. Looking, however, to the closeness of the division on the proposal for a conscience clause and to the fact that three out of four medical men as well as the solitary Royal Commissioner who is on the Committee supported the proposal, we venture to suggest to Mr. CHAPLIN that the decision with regard to penalties for primary vaccination need not necessarily be applied to any clause which may be introduced to provide for revaccination.

Logically, primary vaccination and revaccination should stand on the same footing, but the Bill is more or less illogical already, and logic, like law, is a good servant but may be a bad master. We assume here that the question of revaccination will be raised and that a clause will be proposed for adoption. It would be mere pettish folly on the part of any members of the Committee who believe in vaccination and revaccination but who have been in the minority on the subject of a conscience clause to withdraw now from their support of revaccination. It would be a shame that revaccination should not be voted on, and any clause for this purpose could have incorporated with it a proviso for the acceptance of a declaration of conscientious objection. To omit from the new law a section dealing with the systematic maintenance and encouragement of national revaccination would be a national blunder, but as the legislative requirement of revaccination would be a new one in this country, it might well be accompanied by that right of relief from penalty for refusal of compliance which was so nearly carried in the committee when primary vaccination was under consideration. Mr. CHAPLIN has said that if the new Act is not a success he will return to Parliament again and again for its improvement. With restricted penalties still possible in the case of primary vaccination, and with a conscience clause as to revaccination, it would soon be possible to learn by experience which of the two methods of inducement towards compliance with the law is the more successful and the less provocative of friction and difficulty. If it were to be found — and it would not surprise us to find — that even single penalties could be wisely dispensed with, then no body of men would more heartily welcome the abolition of fines than would the profession of medicine. Their attitude towards the Bill shows that their aim is not to have fines inflicted but to

[1] THE LANCET, May 21st, 1898, p. 1409.

Digitized by Google

have the children and the adults of the land protected against small-pox.

As a step in this direction we may note that on Tuesday last Sir W. PRIESTLEY carried an amendment, against the views of Mr. CHAPLIN, by 17 votes to 12, which would practically reduce the penalties to one. For by this amendment the Committee decided to waive a second prosecution for the same default until the child was of the age of five years, and that even then proceedings would be withheld provided the parent or guardian made a statutory declaration of his objection. This is not very far removed from the spirit of Sir W. FOSTER'S proposal, and if it were to become law it would be almost tantamount to the abolition of compulsion.

ON Tuesday last the London County Council rejected (that is what their action amounted to) by a majority of 2 to 1 the by-law submitted to them by their own committee as a means of dealing with the serious and growing nuisance of street noises in the metropolis, and made it clear that no regulation dealing efficiently with such a matter will ever receive the sanction of the present Council, the consideration of other by-laws dealing with important cognate subjects being at the same time necessarily postponed owing to there not being a sufficient number of councillors present. The by-law which was defeated on the initiative of Mr. STUART, M.P., was admittedly drawn with the concurrence and aid of the Home Office officials, who, as the controllers of the Metropolitan police, would have had a large share in the responsibility of enforcing it. It ran as follows: "No person shall in any street or public place, for the purpose of hawking, selling, or distributing any article, shout or make any loud noise in such a manner as to cause nuisance or annoyance to residents or passengers, or to persons occupying shops, warehouses or offices. Provided that this by-law shall not apply to costermongers or street hawkers, if and so long as by virtue of the Metropolitan Streets Amendment Act, 1867, they are exempted from the operation of Section 6 of the Metropolitan Streets Act, 1867."

This last sentence, by its somewhat cumbrous method of cross-reference, exempts licensed hawkers and makes it perfectly plain that the by-law was aimed not at costermongers who presumably ply their trade in places where their mode of advertising their wares gives no offence, but rather at the persons who yell the attractions offered by the newspapers they seek to sell, either in our busy streets in the afternoons or in our quieter neighbourhoods at night and on Sundays; and also perhaps at some of the irregular and irresponsible criers of coal and other vendibles, who try to trade in places where they are not wanted or expected and where consequently they have to shout to attract attention. To say nothing of those who are lying ill, we have frequently called attention to the positive danger to health to a man carrying on anxious, intellectual work or preoccupied with business cares, whether in his office or in the street, from the incessant irritation caused by the discordant yellings of these street nuisances, and we were prepared to welcome, in company with all decent citizens, a simple workable by-law for the removal of the evil. This the measure rejected by the London County Council seems to us to have been. The objections urged against it were many of them so paltry as to be almost beneath criticism. One reckless suggestion was summarily disposed of by Sir H. B. POLAND, Q.C., a very valuable alderman of the Council, who pointed out that the police-stations could not become filled with men and boys, as another member had suggested, because the procedure would be by summons and not by summary arrest of the offender, and this was by no means the only trivial insinuation of the supporters of Mr. STUART'S amendment. But one argument employed seems to us to strike at the root of all the independence and integrity of the London County Council. It was adduced by a member who is reported to have said that he knew nothing that would subject the Council to so much unpopularity as these by-laws, while another gentleman who supported him said that if the by-laws were passed the chairman of the committee which was responsible for them would be "the most unpopular man in East St. Pancras." We can understand that fear of incurring grave unpopularity in his district might secretly influence the vote of a particular member of any elective body, but we think that respect for his own good name should deter him from avowing it publicly to his fellows. That the possibility of the unpopularity of the body as a whole or of any member of it should be held up as a wholesome and sound argument and as a deterrent from the taking of any particular course of action by the whole body and that the advice so given should pass almost without challenge seems to us a serious matter. Had such an argument weighed with Parliament it might have delayed the Vaccination Acts, the Factory Acts, the Education Acts, and many other measures passed for the public good to the inconvenience and annoyance of many individuals.

That yelling is a necessity to street hawking is an absurdity to anyone who has an elementary knowledge of London. To take newspapers as an example, the regular better-class street-vendors of them—as, for instance, those outside the gateway of the Temple, at Charing-cross, or at Oxford-circus—never shout. The ear-piercing cry of "All the winners" is raised by small boys anxious, no doubt, properly to earn an honest copper, but who certainly have no right to do so at the risk of the peace of the community or to the pain of the sick and suffering; and we have no hesitation in saying that if Mr. STUART and his followers considered the acquirement or loss of votes when they rejected the by-law proposed to them, whether the votes were those of costermongers or of those interested in the cheap and rapid dissemination of betting and racing intelligence, they were actuated by motives unworthy of English municipal life. That they rejected a workable by-law framed for the public health and comfort we firmly believe.

THE thirty-first annual meeting of the Canadian Medical Association will be held in Laval University at Quebec on Aug. 17th, 18th, and 19th next. For all information application should be made to Mr. F. N. G. Starr, general secretary, 471, College-street, Toronto.

Annotations.

"Ne quid nimis."

THE FIVE-HUNDRED-AND-FIFTIETH ANNIVERSARY OF GONVILLE AND CAIUS COLLEGE, CAMBRIDGE.

AN interesting dinner was held at Gonville and Caius College last week to celebrate the five-hundred-and-fiftieth anniversary of the foundation of the College, and so many eminent medical men have received their education there that although the foundation is not a purely medical one in the least, its anniversaries must always have a peculiar interest for our profession. Five hundred and fifty years ago—to quote largely from an interesting statement made at the commemoration service by Dr. N. M. Ferrers, F.R.S., the distinguished Master—Edmund Gonville, the rector of Terrington, in Norfolk, obtained letters patent from Edward III. to found a hall in Cambridge to be called after his own name and to be dedicated "to the honour of the Annunciation of Blessed Mary the Virgin." Gonville Hall was East Anglian throughout, its revenues being derived from ecclesiastical benefices in Norfolk and Suffolk, and for upwards of 200 years it remained the educational centre of those counties. In 1557 the second founder appeared in the person of "that great and generous John Caius," by whose name the College is colloquially known, and again East Anglia supplied both the man and the money. John Caius was born at Norwich in 1510, was admitted into the College in 1529, and in 1533 was elected a Fellow. Six years later he left the College and after studying under Andreas Vesalius graduated in medicine at the University of Padua in 1541, whence he was admitted *ad eundem* to the Cambridge degree in medicine. On his return to England, learned and full of the fame which he enjoyed as friend and equal of the great continental scholars, he became a Fellow of the Royal College of Physicians of London, of which corporation some eight years later he was elected President. In 1557 Dr. John Caius, who had acquired great wealth by his professional practice, obtained from King Philip and Queen Mary the Charter of Foundation as well as of Confirmation by which he was made co-founder of Gonville and Caius College. He presented to the new foundation manors in Hertfordshire and Norfolk and lands and houses in Cambridgeshire. At his own charge he built two wings of the College building and likewise furnished the library with many books of great value. Over the new or joint foundation he placed Mr. Thomas Bacon, the then master of Gonville Hall, but on Mr. Bacon's death in 1559 he was himself "prevailed on by the unanimous request of the Fellows and the solicitation of the Vice-Chancellor and heads of the University to take into his own hands the government of the College." He accepted the post without stipend. In this station he lived and under him the College flourished for thirteen years and upwards, when he resigned the Mastership in 1573. Two months later he died and is now buried in the chapel of his great foundation. Gonville and Caius College may well be proud of its second founder, who was not only a profound scholar and a skilled and painstaking observer, but was also the most important medical author in England before Harvey. So that although the College has a great record in the schools in every direction—and it may be added that Caius men have been particularly successful this year both in classics and mathematics—the predominating influence of the name and fame of John Caius will probably continue to secure to his foundation a large number of the members of the Cambridge University Medical School. It is interesting to note that Dr. Caius is the only man who has ever ruled over a college of his own founding and called by his own name in Cambridge or, we believe, Oxford. The historic families of Sidney, Clare, and Pembroke have all founded colleges which bear their names, but in no case did the founder of these personally rule over the fortunes of the new college, being in two instances at least debarred by her sex if not by her inclination.

KISSING THE BOOK.

AT the Central Criminal Court on June 23rd Mr. Justice Grantham said that the testaments on which witnesses were sworn had been in use for a great many years and he thought that it was time that the proper authorities should supply new ones. No one, however, seemed to know upon whom this duty devolves. A copy of the Gospels can, we believe, be procured for a penny, so it ought not to be difficult to supply new copies, but we earnestly hope that when new ones are supplied advantage will be taken by the judges to point out that the Scotch form of oath is perfectly valid and should invariably be preferred. We need not again go into the arguments against the practice of "kissing the book," and we merely mention the circumstance because it seems to us a favourable opportunity of doing away with the practice altogether.

THE REPORT OF THE PETROLEUM COMMITTEE.

LAST week we ventured the opinion that it was premature to say definitely what decision would be precisely arrived at by the Petroleum Committee, although a good deal of confidence had been expressed in some authoritative quarters that Mr. Collings's report would be accepted with slight amendment. The march of events has proved this speculation to be wrong. It may be remembered that Mr. Collings proposed to deal with the construction of lamps, while Mr. Ure expressed the conviction that it was only by ensuring the supply of burning oil of a flash-point never below 100° F. that safety could be guaranteed. At their meeting last week the committee divided on this issue, with the net result that a majority of one was in favour of Mr. Ure's contention that a minimum limit of 100° F. should be placed upon oil intended for use in lamps. So far, therefore, as the findings of the Petroleum Committee are concerned the momentous question has been decided by one member. Fifteen members voted, the chairman assuming on a division a neutral attitude by not voting at all. It is doubtful whether this result will convince the Government that the conclusion is sufficiently decisive to demand the adoption of the drastic step which such a recommendation implies. One important point at any rate seems to us to have been overlooked. Is the construction of the millions of lamps now in use adapted to burn oil of a minimum flash-point of 100°F. Abel test? We have decided misgivings on this head and if we are right it is evident that the proposal to fix the flash-point at 100° F. will involve new lamps as well as new oil, whereas assuming that the committee had decided that the oil of 73°F. flash-point could be burnt safely in properly constructed lamps legislation would need only to be brought to bear in one direction instead of two. We fully realise the vexatiousness of the problem and the difficulty of suggesting and bringing to a successful issue a way out—that is, one which will be a means of protecting as far as is humanly possible the public from risk and disaster. We have approached the subject solely from the point of view of public protection; we are quite indifferent as to the direction that legislation may eventually take as long as it appears practicable and proves in actual effect to be a preventive measure shielding the public from a source of danger which has undoubtedly increased during

Digitized by Google

recent years. Our attitude is well known and we see no reason for changing it. We have gained practical evidence of the security afforded by properly constructed lamps. We believe the fixing of the flash-point of oil at 100° F. to be impracticable as a basis for legislation, while there are reasons for thinking that its adoption may convey a false sense of safety and lead to even greater carelessness and negligence than have hitherto prevailed. If our attitude should ultimately prove to be wrong we shall none the less welcome any alternative proposal, should it be followed by a happy issue, from whatever lines of reasoning it may have sprung. Let the flash-point be raised by all means if that will protect life and limb and if at the same time it will not engender other hardships in the every-day conduct of human affairs.

THE SMOKE NUISANCE.

LAST week we expressed disagreement with the judgment given by Sir James Vaughan in a case of smoke nuisance. The magistrate said that he was satisfied that the company summoned had done all in their power to mitigate the nuisance and he accordingly marked the summons "No conviction." A precisely similar line of defence, that is, that the nuisance was caused through the difficulty of getting smokeless or Welsh coal owing to the strike, was adopted at Westminster this week, but Mr. Sheil said: "That is no defence. The full penalty is £10. I will fine the defendants £5 and 23*s.* costs." That is precisely our view, which was expressed almost exactly in the same terms on page 1768 of our last issue.

DINNER OF THE EPIDEMIOLOGICAL SOCIETY.

A VERY successful dinner of this society was held on Friday, June 24th, in the Marble Saloon of the Grand Hotel, Trafalgar-square, the President, Professor Lane Notter, being in the chair. Amongst those present were Sir Walter Foster, M.P., Surgeon-Major-General James Jameson, C.B., Director-General of the Army Medical Department, Mr. Shirley Murphy, Dr. Franklin Parsons (President elect of the Epidemiological Society), Dr. Whitelegge, Her Majesty's Chief Inspector of Factories, Dr. Klein, F.R.S., Surgeon-Colonel Stevenson, A.M.D., Mr. Gough, Secretary of the Thames Conservancy Board, Dr. Blake, L.C.C., Dr. Newsholme, Dr. Sweeting, Dr. Hector Mackenzie, Dr. Washbourn, Dr. F. W. Andrewes, Fleet-Surgeon Theodore Preston, R.N., Brigade-Surgeon J. B. Scriven, and many others. The toast of "The Army and Navy" was proposed by Sir Walter Foster, M.P., who congratulated the Army Medical Department upon the reform which they had already obtained and insisted upon the paramount importance of unity of action in the medical profession where the welfare of any of its numerous branches was concerned. The toast was responded to by the Director-General of the Army Medical Department and by Fleet-Surgeon Theodore Preston, R.N. Dr. Whitelegge proposed the toast of "The Visitors" and, coupling it with the names of Dr. Blake of the Public Health Committee of the London County Council and Mr. Gough of the Thames Conservancy Board, drew attention to the great influence which both the London County Council and the Thames Conservancy Board must of necessity exercise upon the health of the metropolis. In the course of his reply to the toast, Mr. Gough gave a very interesting account of the work done by the Thames Conservancy, which he stated was the oldest authority for the prevention of water pollution, powers having been conferred upon it by the Legislature in 1866. These powers, however, being limited to the main stream and parts of tributaries, within three miles of the main stream were found insufficient and, as a result of a recommendation of Lord Balfour's Commission, the Conservators have now jurisdiction *re* pollution over a much wider area. Mr. Gough referred to the excellent results which had been obtained in the tideway by the efforts of the London County Council in the treatment of the metropolitan sewage, while above the western limits of the metropolis the Conservators have constantly at work a chief inspector, seven inspectors, and eight assistants, reports being received from these officers on every aggregation of houses in the area. Samples of water, which last year amounted to 1500, are constantly submitted to the Board's analyst, Mr. C. E. Groves, F.R.S., and it appears that the amount of organic impurity dissolved in the water immediately above the intakes is now only about two-thirds of that which it was prior to 1894, when increased powers were conferred upon the board. The toast of "The Epidemiological Society" was proposed by the President, who dwelt upon the work done by the society and urged the desirability of its keeping in the main to the scientific aspect of epidemiology. He announced amid much applause that it had been unanimously resolved to confer the first "Jenner Medal" upon Mr. William Henry Power, F.R.S., whose work was regarded as being a type of that which the society should seek to honour. Mr. Shirley Murphy, in proposing "The Chairman," thanked Professor Notter for the very valuable advice and guidance which he had afforded to the society during his term of office, and congratulated the council upon their selection of the first Jenner Medallist.

SANITATION VINDICATED.

WHEN the *tout à l'égout* system was first inaugurated in Paris its opponents were numerous and bigoted. It was absurd, they said, to expect that sewage could be purified by pouring it over land, and as for the notion that agricultural advantage would accrue it was simply visionary. Hygienists, like all would-be reformers, were blindly zealous, utterly unable to perceive defects in their precious bantling, and obstinately incapable of letting well alone. If allowed to proceed with this monstrous scheme they would end by creating a centre of infection which would eventually poison the entire city. Facts, however, are stubborn things, and the experiment at Gennevilliers has been so successful that the more reasonable among the early decriers have been converted. The sewage farm at Achères occupies as it were a peninsula formed by the winding Seine and covers about 2470 acres. Each half-year the quantity of sewage dealt with amounts to 20,000,000 cubic metres, but so perfectly is the work done that in spite of this enormous deluge there is no local nuisance whatever and the neighbourhood is remarkably healthy. The great project for purifying Paris has only been partially executed, but even though it were as complete as the projectors desire a minority of detractors would doubtless still raise their voices in depreciation. Notwithstanding the immense benefit conferred on Paris by the actually existing drains there are not wanting people who stigmatise them as so many elongated cesspits in which the movement is so slow that it takes the sewage two or three weeks to reach Clichy. As a writer in *La France* lately put it: "The circulation of the noxious matter is so languid that viscous fermentable deposits must necessarily take place to an extent which cannot but be in the highest degree dangerous to the public health." As usual, the anti-hygienists first beg the question and then triumphantly proclaim the logical conclusion. But, as already said, facts are stubborn things, and M. Bechmann, and M. Launay, the manager and chief engineer of the sewage works, have been fortunately able to demonstrate the unsoundness of their opponents' arguments by means of an object lesson as striking as it is decisive. During the Easter fêtes the streets of Paris were thickly strewn with *confetti*, just as though a violent storm of indissoluble

Digitized by Google

hailstones had been raging. The sweeping of the main boulevards began next day at three o'clock in the morning, and before eleven o'clock in the forenoon the *confetti* commenced to put in an appearance at Clichy. By midday the fields at Achères were covered with them. Instead of three weeks the transit occupied about eight hours, the distance measured from the Austerlitz bridge being a little over five miles. As the writer of an article on the subject in a Parisian medical paper remarks, "This original demonstration seems to be decisive."[1]

THE CRYPT OF ST. GEORGE THE MARTYR.

THE Home Secretary, upon the report made to him by Dr. Hoffman, Inspector of Burial Grounds, as to the condition of this crypt, has, we are very glad to announce, ordered the Vestry to remove the bodies which are lying there. At a meeting of the vestry of St. George's, Southwark, held subsequently to the receipt of the official direction from the Home Office, a prolonged and heated debate terminated in the passing of a resolution with one dissentient voice only to the effect that "the vestry as the elected representative of the parishioners of St. George the Martyr, Southwark, regret the action taken by the Home Secretary with regard to the crypt without first giving the sanitary authority of the district an opportunity of being heard, and they now request that a deputation of the vestry on the subject should be received by the Secretary of State." We certainly should like to hear what arguments the vestry can adduce to prove that it is for the good of the community over whose interests they have been chosen to preside that the crypt under the church of St. George the Martyr should remain full of corpses, but probably we never shall hear them, as it is unlikely that the Home Secretary will receive the deputation.

NOMENCLATURE OF NOTIFIABLE DISEASES.

THE vestry of St. Marylebone has memorialised the London County Council for the inclusion among the notifiable diseases of metritis and peritonitis following labour, and of puerperal pyæmia, septicæmia, and sapræmia, alleging that by employing these terms many medical men evade the notification as puerperal fever of cases which would otherwise be described as such and escape the discredit which would attach to the occurrence of such unfortunate accidents in their practice, though it is evident that if all were like-minded there would be nothing left to notify under this head and the purpose of the Act—that of calling the attention of the medical officer of health of the district to the existence in a house of a most "dangerous infectious disease" capable of being conveyed by the medical attendant or nurse to other parturient women and demanding special precautions to prevent its spread—would be completely defeated. The expression "puerperal fever," though from a strictly scientific standpoint inaccurate and, perhaps, indefensible, presents the practical advantage of being generally understood and, though vague, of being sufficiently comprehensive to cover every form of blood-poisoning, whether derived from internal or external sources, occurring during or subsequently to parturition and all in the highest degree infective. Metritis and peritonitis arising under these circumstances being always of septic origin, the distinction between sapræmia and septicæmia being, so to say, academic, and "pyæmia," so-called, being but septicæmia which has led to embolism, thrombosis, and the formation of abscesses and necrosis, "puerperal septicæmia" would seem to be the most appropriate as a general designation, but, as we have said, "puerperal fever" is after all the best as being intelligible to the public. This question is, however, really only part of a larger one, and the same practical considerations are applicable to the nomenclature of other infectious diseases, notably so to the infective sore-throats, pharyngeal and laryngeal, comprehended under the appellations of "diphtheria," "diphtheritic sore-throats," "croup," and other semi-scientific or popular expressions. The obvious and only practicable means of precluding evasions of the Act is to be found in an amendment of the schedule by the addition of synonyms and definitions both inclusive and exclusive, as for example—

Cholera.—Asiatic (not the so-called English, cholera nostras, infantum, and choleraic diarrhœa, cholerine, &c.).

Diphtheria.—Pharyngeal, laryngeal, nasal, &c. (including so-called diphtheritic and infectious sore-throats, membranous and infectious croup, but not catarrhal, non-infectious, and "spasmodic" croup).

Puerperal fever (including all septic, febrile, and inflammatory sequelæ or complications of, and consequent on, parturition).

[1] Le Progrès Médical, May 21st, 1898.

GLOSSITIS IN TYPHOID FEVER.

IN the *Johns Hopkins Bulletin*, May, 1898, Dr. Thomas McCree has described a case of this very rare complication which occurred in Dr. Osler's clinic. A man, aged twenty-seven, was admitted for a mild attack of typhoid fever from which he made a complete recovery. He was discharged after his temperature had been normal for 22 days. He was readmitted in 4 days complaining of pain in the throat, soreness, and swelling of the tongue, which had followed a chill on the previous day. The temperature was 104·2° F., the pulse was 100, the face was flushed, the neck was full and swollen at the angles of the jaws. The mouth presented a striking picture. The tongue was much swollen and protruded between the teeth, preventing the closure of the mouth; it was red, indurated, and tender. There were profuse salivation and dysphagia. The swelling gradually subsided and passed away in 3 days. The patient had a typical relapse of typhoid fever, pyrexia, rose spots, and enlarged spleen, which ran its course in 2 weeks. Cultures made from punctures of the tongue were negative. The punctures seemed to help to reduce the swelling.

THE LONDON SOCIETY OF MASTER PLUMBERS.

THE medical profession cannot fail to recognise the importance of craft associations which are formed with a view of upholding the dignity and position of the professions concerned, and more particularly must this be so when the trade or profession happens to be one upon the work of which the sanitary condition of our towns and villages very largely depends. This is so with the plumbing fraternity, and the London Society of Master Plumbers is an association with commendable objects aiming to secure for the plumber that status which his skill should demand and for the public an efficient and reliable workman. No class, perhaps, has been so roundly abused as the plumber and in many instances it is to be feared that this abuse was justified. The fact is, the merest dabbler in lead work who could make some sort of a joint or stop a leak called himself a plumber, though he was quite without any training, much less qualification, so to practise. Much mischief has been done in this way by the public themselves by ignoring the extreme importance of thorough work, but fortunately for the country there has recently sprung up a strong feeling that in the interests of the sanitary condition of our houses a system should be instituted which should offer some security that all sanitary arrangements may be placed in the hands of competent men. As is well known, the Worshipful Company of Plumbers is doing excellent work in this direction and during the last four years a practical association called the London Society of

Digitized by Google

Master Plumbers has been extending similar good offices throughout the country. The association numbers 1000 members and at the annual dinner held at the Holborn Restaurant on June 28th the secretary announced a decided increase in the membership. Everyone with any concern at all for sound sanitary work will wish the association every possible success and none can doubt the worthiness and excellence of its purposes.

THE JENNER MEMORIAL.

THE Jubilee year necessarily interrupted this movement and many others. The committee charged with the duty of promoting a work of national utility in honour of Edward Jenner in connexion with the British Institute of Preventive Medicine, to be distinguished by Jenner's name and devoted to researches on the lines which he initiated, is now at work again. We must all feel anxious for its success. There is every reason why Jenner's fame should be reaffirmed by every intelligent man and woman who values life and researches into the subtle means by which epidemics of all sorts can be as effectually checkmated as Jenner's discovery checkmated small-pox. It should be clearly recognised that Jenner's fame is in no danger. "The civilised world" has taken that into its care. It is the national reputation of Englishmen for common sense and for reverence for their best teachers that is at stake. It will be a bitter reflection for them one of these days to perceive that other nations guard the fame of England's great son and enjoy the exemption from small-pox which we shall lose proportionately as we dishonour him.

TOTAL EXTIRPATION OF THE STOMACH WITH ŒSOPHAGO-ENTEROSTOMY.

IN THE LANCET of Jan. 15th, 1898, we published Dr. C. Schlatter's case—the first in which this operation has been performed. Some cases had been previously recorded as extirpation of the stomach but they were only partial resections. In the *Boston Medical and Surgical Journal*, May 5th, 1898, Dr. C. Brigham has published a second case. The patient was a woman, aged sixty-six years, who had suffered from pain in the stomach for a year and from vomiting of solid food for two months. On a liquid diet she was able to keep to her usual weight, 135 lb., and she was remarkably healthy. There were hardness and tenderness in the pyloric region. The operation performed was not the same as in the first case. When the stomach had been removed Dr. Brigham found that the ends of the œsophagus and duodenum could be brought together without undue tension. As the pulse had become weak from the length of the operation they were united by the Murphy button (œsophago-duodenostomy). In the first case, on the contrary, Dr. Schlatter could only bring the ends together with difficulty; he therefore united the œsophagus laterally to the intestine about 12 in. below the duodeno-jejunal fold (œsophago-jejunostomy). In Dr. Brigham's case the growth was at the pyloric extremity and extended over more than half the stomach. The pyloric orifice was so reduced that only a sound could be introduced. The patient made a good recovery. Water was administered by the mouth on the day after the operation, and other fluids were then given. Deglutition was at times painful. On the eighteenth day solid food was given. At the time of the last report (7 weeks after operation) the patient was eating well, gaining in weight, and was able to walk. Dr. Brigham attributes the occasional dysphagia to the Murphy button, which he thinks had better be dispensed with if possible. At no time was undigested food passed in the motions, which exactly agrees with Dr. Schlatter's observations. These cases therefore confirm what has already been shown by experiments on animals and by observations on certain patients in whom secretion of gastric juice was deficient or absent, that digestion may be completed without the aid of the stomach. Dr. Brigham seems to have had an ideal subject for operation in respect to her general condition. This preservation of health and, above all, of weight by a patient with advanced cancer of the stomach is exceptional.

QUACKS.

ON June 23rd Henry Thomas Kirk Richards was sentenced at the Central Criminal Court to three years' penal servitude for obtaining money by fraud from people in different parts of the country by advertising an inhaler to cure deafness and medical pills to cure female ailments. The judge said that it was impossible to conceive what harm prisoner might do to persons whom he supplied with his quack remedies. We heartily congratulate the Common Serjeant on his dictum; but we desire to know why Munyon, Mother Siegel, Warner, Madame Frain, and all the other advertising quacks should go scot free. Still more, why should "Dr. Bell" and the various "Reverends" be allowed to deceive persons, even though fools, without being punished? If Richards alone is punished it will be unfair. We fear, from the reports of the trial in the daily press, that Richards's illegality technically consisted in not as a rule sending his remedies. This, we think, is a point in his favour, but apparently he sometimes did send them, or the Common Serjeant would not have spoken as he is reported to have done.

THE RED CROSS SOCIETY AND THE SOUDAN CAMPAIGN.

THE refusal to allow the English Red Cross Society to participate in the Nile expedition raises the question as to the position which that society occupies. It may be urged that the medical department of an army should suffice for the need of that army. This, indeed, is the position taken up by the Sirdar and by Lord Cromer. The latter, in his answer to Lord Wantage, the chairman of the English Red Cross Society, says that "very ample arrangements have been made for the sick and wounded and that to accept the offer would involve heavy call on transport beyond that for which calculation is made. This would necessitate diminishing the number of fighting men, which would be very considerable. We are, therefore, unable to accept." Lord Wantage, in reply to this refusal, explains that in 1884–85 two steamers were fully equipped by the society for service on the Nile and an additional steamer was lent by an English gentleman for transport purposes on the Red Sea. The Red Cross Society spent on that occasion £34,000 and comforts and luxuries were supplied which, it is claimed, have never been so fully provided by the army authorities. The position taken up by the Red Cross Society is that it increases the amount of aid which the regulations of the army allow, gives greater luxuries to the sick and wounded, and all this is done without augmenting the burdens of the taxpayer. The Red Cross Society affords the benevolent an opportunity of helping to mitigate the horrors of war. So far the Red Cross Society has worked in harmony with the authorities of the army, but now, for the first time, its services have been refused. It is true that on this occasion distance and difficulties of transport are exceptionally great, but a vast colonial empire must ever face such obstacles. Again, if the Red Cross Society is to render practical service it should lose no chance of acquiring practical experience. Far from seeking to burden the military authorities the Red Cross Society pays its own expenses and provides its own ships and means of transport. Presumably, however, there are some things which it cannot provide. It cannot increase the

Digitized by Google

limited rolling-stock for the railway lines laid down in the desert, nor can it supply the military escort that may be necessary to protect its ambulances against the raids of the Dervishes. Perhaps, therefore, there may be substantial reasons for refusing the proffered aid on this occasion, but if so it should be clearly understood and stated that this is altogether an exceptional case. Otherwise, what is the use of the Red Cross Society? In another column some details are given of the great services rendered by the Spanish Red Cross Society in Cuba and elsewhere. What a poor country like Spain has been able to accomplish the wealthy British nation should do on a much larger scale and it is quite easy to understand the disappointment which is now felt by the members of the English Red Cross Society. If it is really impossible to accept their services no pains should be spared to render it evident that there is no desire to discourage their generous and humanitarian efforts.

INSANITARY HOUSE PROPERTY IN HONG-KONG.

IN general the greater the sub-division of a Chinese tenement house the larger the revenue it will produce, but in Hong-Kong it is now proposed to place restrictions on excessive sub-division. The Insanitary Properties Commission have presented a report from the abstract of which, published in the *Hong-Kong Weekly Press*, it appears that all five commissioners are agreed that in houses fronting streets less than 15 ft. in width no cubicles should be allowed on the ground floors; three are of opinion that in such houses no cubicles at all should be allowed and two are of opinion that in houses fronting on lanes and streets of over 15 ft. no cubicles should be allowed on the ground floor without the permission of the Sanitary Board. It is also recommended that an open space of not less than 40 square feet should be provided at the rear of all houses, even back-to-back houses. At the meeting of the Hong-Kong Sanitary Board held on May 6th, the principal civil medical officer (Dr. J. M. Atkinson) presiding, arrangements were made for granting compensation to the owners or occupiers of a number of insanitary and illegal cubicles and cocklofts which had been destroyed.

CONGENITAL OBSTRUCTION OF THE LARYNX.

AN increasing number of observations tend to show that congenital obstruction of the larynx is neither so rare a disease of childhood nor of necessity so dangerous as might be supposed. The clinical and pathological conditions accurately described by Dr. D. B. Lees in the Transactions of the Pathological Society of London of 1883 appear to be fairly constant. His observations have since been confirmed by the experience of others, for a brief *résumé* of which we cannot do better than refer our readers to the interesting paper published in THE LANCET of Sept. 11th, 1897, by Dr. G. A. Sutherland and Dr. H. Lambert Lack. The subject has again been recently discussed in the *Journal de Clinique et de Thérapeutique Infantiles* by Dr. G. Variot who records a case. The patient was a child, aged twenty-two months. The usual symptoms were present, including croaking inspiration, much less noticeable during sleep but becoming well marked on excitement and associated with clear vocal utterance. This child died from broncho-pneumonia soon after she came under treatment. A post-mortem examination showed the epiglottis characteristically folded together and the ary-epiglottidean folds in contact with each other. The vocal cords were normal. The treatment of such cases must naturally depend upon the view which is taken as to their causation and their prognosis. Dr. Variot is unable in face of the anatomical conditions present to agree with those who regard the respiratory difficulty as purely spasmodic, and he even goes so far as to suggest an operation for the partial resection of the obstructing folds of membrane in cases where an accurate laryngoscopic diagnosis has been arrived at. In this connexion it is noteworthy that Dr. Lees and also Dr. Sutherland and Dr. Lack have recorded a not uncommon tendency towards spontaneous disappearance of the stridor. This result is attained under favourable conditions by the end of the second year or even before then. It is also remarkable that the improvement is associated with persistence of the local constriction. Such facts as these may naturally be expected to qualify the urgent necessity of operative interference in this class of cases, at all events until time has been allowed for some enlargement in the size of the infantile larynx. In the meantime every care must of course be taken to ensure good general nutrition, to prevent the risks of laryngitis, bronchitis, and laryngeal spasm, to deal promptly with any surgical emergency arising out of these, and thus to afford nature all possible help in her curative efforts.

THE VALUE OF THE CHRONOLOGICAL SUMMARY.

THE chronological summary of Chicago mortality from 1851 to date, first published by the Commissioner of Health in his second annual report—that for 1894—is developing new uses. Believing that surgical intervention must have reduced the mortality from cancer of the uterus of late years, Dr. Anson L. Clark, Dean of the Bennett Medical College, recently applied to the Department for the data necessary to test his belief. The following facts and figures compiled from the summary were promptly furnished him. Cancer deaths were first reported in Chicago by organs or parts in 1867; prior to that year only the annual total of all deaths from cancer are on record. The reported number of all deaths from cancer and of deaths from cancer of the uterus are here given by years since that date—the year 1879 being omitted from the table because there is an obvious error in the printed report of that year, only four deaths from cancer of the uterus being reported out of a total of 176 from all cancer. It will be seen that the proportion of deaths from uterine cancer to that from all cases of cancer has diminished in each decennium, the percentages being 21·2, 19·4, and 16·0.

THE ASSOCIATION OF BRITISH POSTAL MEDICAL OFFICERS.

THIS association held its annual dinner at the Hôtel Métropole on June 23rd, Dr. Henry Fitzgibbon, President, being in the chair. Members of the association from all parts of the kingdom were present, besides important guests, including Sir Walter Foster, M.P., Major-General Hailes, Sir Robert Hunter (solicitor to Her Majesty's Post Office), Sir W. H. Wills, Bart., M.P., Mr. H. Osborne Harley,

Digitized by Google

Postmaster of Manchester, Sir William Mac Cormac, Sir Thomas Roe, Sir Hugh Gilzean Reid, Mr. Edmund Owen, Dr. W. Christopher Arnison, Sir Dyce Duckworth, and Mr. Ebenezer Davies, J.P. The association seems in a healthy and prosperous way and alive to the advantages of organisation, though it was modest in the assertion of either its grievances or its wants. One of the features of the evening was a quotation by the chairman in proposing the health of Her Majesty the Queen, of words which he attributed to Nicholas Rowe and which he rightly thought most happily prophetic and expressive of the great and gentle rule of Queen Victoria. They were as follows:—

Of Royal race a British Queen shall rise,
Great, gracious, pious, fortunate, and wise.
To distant lands she shall extend her fame
And leave to latter times a mighty name.
Tyrants shall fall and faithless kings shall bleed,
And groaning nations by her arms be freed.
But, chief, this happy land her care shall prove
And find from her a more than mother's love.
From hostile rage she shall preserve it free,
Safe in the compass of her ambient sea.
Though famed her arms in many a cruel fight,
Yet most in peaceful arts she shall delight,
And *her* chief glory shall be to unite.
Picts, Saxons, Angles shall no more be known,
But Britons be the noble name alone.
With joy their ancient hate they shall forego,
While Discord hides her baleful head below.
Mercy and Truth and Right she shall maintain
And every virtue crowd to grace her reign.
Auspicious Heaven on all her days shall smile
And with eternal Union bless her British Isle.

THE SANITARY INSTITUTE: THE SIXTEENTH CONGRESS.

THE preliminary programme of the Sixteenth Congress of the Sanitary Institute, to be held in Birmingham under the presidency of Sir Joseph Fayrer from Sept. 27th to Oct. 1st, has now been issued. Dr. Christopher Childs, M.A., D.P.H., will deliver the lecture to the meeting in plenary Congress, and Dr. Alexander Hill, M.A., J.P., Master of Downing College and Vice-Chancellor of Cambridge University, will deliver the Popular Lecture. The Congress will include three sections, meeting for two days each and dealing with (1) Sanitary Science and Preventive Medicine, presided over by Dr. Alfred Hill of Birmingham; (2) Engineering and Architecture, presided over by Mr. W. Henman, F.R.I.B.A.; (3) Physics, Chemistry, and Biology, presided over by Dr. Sims Woodhead. Five special conferences will also be held: (1) Municipal Representatives, presided over by Alderman W. Cook, Chairman of the Health Committee of the Birmingham City Council; (2) Medical Officers of Health, presided over by Dr. John C. McVail, Medical Officer of Health of Glasgow; (3) Municipal and County Engineers, presided over by Mr. T. de Courcy Meade, M.Inst.C.E.; (4) Sanitary Inspectors, presided over by Mr. W. W. West, Chief Sanitary Inspector, Walthamstow; and (5) Domestic Hygiene, presided over by Mrs. C. G. Beale, the Lady Mayoress of Birmingham.

A COLLEGE FOR MEDICAL MISSIONARIES.

ON June 22nd a small committee, comprising the Bishop of Bristol, the Bishop of Wakefield, the Earl of Stamford, Sir William Paget Bowman, and several members of the medical profession, met at the house of Dr. Symes Thompson, Provost of the Guild of St. Luke, to discuss the scheme of founding a residential college in London where English Churchmen who intend to act as medical missionaries could reside while pursuing their professional education at one or other of the London medical schools. The scheme has long been under the consideration of the Guild of St. Luke and the meeting was convened in order to obtain an expression of opinion on the part of the dignitaries of the Church and some of the leaders of the profession as to its utility and the best mode of carrying it into effect. The proposed College will be controlled by the Council of the Guild of St. Luke and under the immediate management of two officers — a principal (who will be a medical man) and a chaplain (who will be a clergyman of the Church of England). They will assist and guide the students. When necessary the scholars will receive pecuniary aid from the College funds. It is intended that the students of the College shall become fully-qualified practitioners before taking up missionary work and shall acquire special knowledge of tropical diseases and sanitary science. While they will be missionaries they will not be in holy orders. The meeting was cordially in favour of the scheme and the opinion was generally expressed that the time had come for vigorous action. Various details were discussed and it was determined that strenuous efforts should be made to raise the necessary funds. Many letters expressing approval were read, but as the project has evoked so much sympathy it is impossible to give a list of the names of the writers. We may however mention among the supporters of the scheme the Archbishop of Canterbury, the Archbishop of York, the Bishop of London, the Bishop of Rochester, the Bishop of Bristol, the Bishop of Wakefield, Sir Henry Acland, Sir William Broadbent, Sir Joseph Fayrer, Sir Dyce Duckworth, and many other well-known physicians and surgeons.

THE PECULIAR PEOPLE.

AT the Old Bailey recently Mr. Justice Darling tried one of those curious cases which occur occasionally in which members of the sect calling themselves the Peculiar People find themselves the object of prosecutions which to them doubtless seem to be mere persecution. In this particular instance the accused had suffered his child to die from pneumonia rather than call in medical aid to supplement the anointing with oil and laying on of hands performed by an elder of his church. He was convicted of manslaughter and received no punishment beyond being bound over to come up for judgment when called upon. It may be that his lordship thought that the fear of the enforcement of this penalty would deter him from allowing another child's life to be sacrificed to his doubtless sincere convictions; but we are inclined to doubt the correctness of such a view when we consider the evidence given by the prisoner himself before the coroner and read over during his trial at the Central Criminal Court. He then said that he had some years ago lost another child who had died *without medical aid being summoned and on whom no inquest was held*. The Peculiar People show no tendency to be untruthful, so this statement is probably perfectly true, but it may be asked how in such a case the child came to be buried without inquiry, whether a certificate of the cause of death was given, and if so by whom, and why? We also wonder whether Mr. Justice Darling had this previous death in his mind when he passed sentence.

THE CHESTERFIELD HOSPITAL AND MEDICAL CASES.

IN another column will be found a letter from Dr. John Rose upon this important question. The matter as it stands is briefly thus. Chesterfield and district contain a population of 145,000. There is no provision for the gratuitous treatment of medical as opposed to surgical cases except the workhouse infirmary. The Chesterfield Hospital contains room for 60 ordinary beds, but on an emergency—e.g., a bad colliery accident—these 60 beds can be increased to 84. The average number of beds occupied is 30, so that 30 ordinary beds and 54 emergency beds are empty. The advocates of admission for medical cases submit that the 30 unoccupied beds might be used for medical cases. The

Digitized by Google

governors of the hospital, however, say that the hospital constitution forbids the admission of medical cases and they cannot break the rules. But they have already broken one of them (Rule 2), which runs as follows: "The hospital shall be open to receive only those persons requiring surgical treatment. Cases of disease or sickness in any form and chronic cases shall be excluded." This definition would at once exclude all cases such as tuberculous diseases of joints, all tumours, and, in fact, only cases of injury could be treated. And yet other cases than injuries have been treated. It being apparently impossible to get medical cases admitted to the hospital, efforts have been made to build a new medical hospital. At present all medical cases have to be sent to either Sheffield or Derby. In our issue of May 15th, 1897, we commented upon the proposal to erect a drill-hall as a Jubilee memorial at Chesterfield, when it was decided that any surplus should be devoted to forming the nucleus of a fund for a medical hospital. We do not know whether there was a surplus or not, but the medical hospital is still *in nubibus*. To our minds the building of a separate hospital involves a waste of time and energy: the two classes of cases had much better be treated under one roof; but provision for the care of those suffering from, say, pneumonia, bronchitis, or rheumatic fever, or even enteric fever, must be made without delay if Chesterfield desires to preserve the reputation of the North for hard-headed common sense.

THE REPORT OF THE METROPOLITAN ASYLUMS BOARD.

THE annual report of the Metropolitan Asylums Board for the year ended March 25th, 1898, contains a new feature of great interest—namely, an account of the steps taken by the Board to provide for certain classes of children the care of whom had hitherto devolved upon boards of guardians. Such are (*a*) those suffering from ophthalmia or other contagious diseases of the eye; (*b*) those suffering from contagious diseases of the skin; (*c*) those requiring special treatment during convalescence; (*d*) feeble-minded and defective children; (*e*) those ordered by a magistrate to be sent to an industrial school or asylum. For class (*a*) sites have been acquired near Brentwood and at Swanley for the erection of suitable schools. Provision for class (*b*) is still under consideration. Class (*d*) is to be provided for by cottage homes which are to be rented in the vicinity of the special schools provided by the London School Board. About 60 children will be provided for in the first instance. With regard to infectious diseases, the cases of diphtheria admitted to the hospitals was for 1897 6592, an increase over the figures for 1896 of 1358. The number of notifications, however, for 1897 was less by 559 than the number of notifications in 1896. It is fair therefore to assume that the prejudice formerly felt with regard to removing patients to hospital is dying out. The percentage mortality of this disease was only 17·7 during 1897. In 1894 it was 29·3. This marked diminution in fatality coincides with the spread of the use of antitoxin. The new Park Hospital was formally opened and the Board has acquired a site upon the Thames Embankment for the erection of new offices.

PSEUDOBULBAR PARALYSIS WITH DIPLEGIA IN A CHILD.

AT the Verein für Psychiatrie und Neurologie in Vienna[1] in November of last year Dr. von Sölder showed a curious case. The patient was a child, aged nine years, whose birth was normal and at full time, and who, during the first five years of her life was healthy both in mind and body. In her sixth year she began to have difficulty in walking, the result apparently of some defect in the right leg and her speech was also interfered with. Later there was weakness of the right arm and in the following year of the left leg, and about this time there was interference with the act of mastication. For more than a year before the time at which the patient was shown there had been difficulty in using the left arm and a little also in swallowing. The gait was now spastic with left talipes equinovarus, and pronation of the right foot. There were lordosis and unsteadiness, and during walking some athetotic movements of the upper extremities and of the lower part of the face—the latter movements being also present in some degree during rest. There was great weakness of the arms and marked spasticity existed in the legs. The knee-jerks were active, the right more so than the left. The speech was bulbar in character, almost unintelligible, and the orbicularis oris and the masticatory muscles were paretic. The act of swallowing was itself apparently not much interfered with and there were no electrical changes in the facial muscles. Dr. von Sölder regarded the case as one of cerebral affection, but the late onset and the slow development of the condition are both noteworthy.

THE RÔLE AND ETHICS OF MUSIC.

IN no better way can a nation express its gladness than in music and, besides, a well-conducted performance of the choicest excerpts from the great masters is a delight to all concerned and of distinct benefit as a factor in mental recreation. Viewed in this light, the Grand Festival Concert held at the Crystal Palace on June 25th in honour of the sixtieth anniversary of the coronation of Her Majesty the Queen-Empress was an unqualified success and highly appreciated by an audience of over 22,000 persons. Such could hardly have failed to be the case in view of the character of the programme provided and of the promised appearance of such excellent soloists as Madame Adelina Patti, Miss Clara Butt, Mr. Edward Lloyd, and Mr. Santley. The chorus numbered 3000 voices, consisting of the London contingent of the Handel Festival choir and an orchestra of 500 performers. We welcome events of this kind and on this scale—a scale which cannot be less if such works as the "Hailstone Chorus," from Handel's *Israel in Egypt*, or the "Dies Iræ" from Berlioz' *Grand Requiem* are to approach anything like that completeness which the respective composers meant to convey; and it is gratifying to learn from the experience of these occasions that the public, as evidenced by an expanding attendance, are evincing more and more a taste for that class of music which kindles the noblest feelings and fosters the healthiest aspirations in the human mind. This fact points to a wholesome desire for mental rest engendered by the ever-increasing pace and demands of modern existence, and the music-providing section in our midst deserve every encouragement at the hands of the public to persevere in thus ministering to this need. Music is an influence for good, and as Auerbach has said, "Music washes away from the soul the dust of every-day life," and the increasing demand for its enjoyment as shown at our great public performances is a distinct and sure indication of the healthy and moral progress of the nation.

SIR FRANCIS SEYMOUR HADEN will preside at the twentieth annual meeting of the Church of England Burial, Funeral, and Mourning Reform Association to be held at 32, Wimpole-street, on Wednesday, July 6th. Among other resolutions will be one pointing out the desirability of the clergy enforcing the Christian obligation of carrying out the burial of the dead promptly, innocuously, and inexpensively.

MR. WILLIAM GABRIEL ROCKWOOD, M.D. (Madras), has been appointed an Unofficial Member of the Legislative Council of the Island of Ceylon.

HOSPITAL REFORM.

A SPECIAL meeting of the Council of the Charity Organisation Society was held on June 20th at the United Services Institution to discuss suggestions for the reform of the casualty and out-patient departments of London hospitals. Sir JOSHUA FITCH was in the chair and there was a large attendance.

Mr. T. CLINTON DENT, surgeon to St. George's Hospital, described an experiment which is about to be made in connexion with the New Belgrave Hospital for Children. It was proposed to guard against the overgrowth of the number of out-patients by limitation of new cases and selection and at the same time to place a check upon the undue multiplication of casualty patients. Mr. Dent pointed out that unless this were done any rule limiting the number of out-patients, however strictly observed, would be useless. Although the number of applicants in the surgery of a children's hospital was infinitely smaller than in a general hospital, it was of equal importance to avoid the treatment of ineligible cases and to prevent the surgery from becoming a vicarious out-patient department. Of course, if a case brought to the surgery was so serious that it could not be sent away it would have to be admitted to the in-patient department; but generally speaking the same inquiry would be made in the surgery as in the out-patient department as to the circumstances of the parents and the same regulations would apply. The chief difficulty in a children's hospital was to guard against indiscriminate prescribing. Mr. Dent contested the view that every patient who applied as a "medical casualty" must necessarily receive treatment.

Mr. Dent described in detail the measures which were proposed for the limitation and selection of cases. The number of new cases to be seen by the medical officer at each attendance would be limited to fifteen. Preference would be given first to the most serious and acute cases. Next in order of preference would come those recommended by medical practitioners, while third in order would come those bearing certificates from governors of the hospital. It was not likely that this last class would be numerous, but great importance would be attached to the recommendations of medical practitioners. In fact, the principle underlying the whole scheme was the desire to work with, and not in antagonism to, the general practitioner. The best possible arrangement in his opinion would be for the general practitioner to be practically the almoner of the charity, as no one would probably be so well qualified to judge of the necessities of the case or better informed as to the circumstances of the parents. As to this point it was intended to employ an inquiry officer as an experiment. The benefits of the hospital would also be guarded by a wage-limit estimated on the proportion of the family income to the family. The wage-limit had been purposely fixed low in order that the benefits of the hospital might go to the very poor, for whom they were intended. A register would be kept of the out-patients setting forth age, name, and address, the dates of admission and discharge, and the occupations and wages of the parents. This register would be open for the inspection of local practitioners and the representatives of charitable institutions.

The most novel feature in the new scheme was an arrangement by which the hospital should be available for consultation by people who, though able and willing to pay the moderate fees of general practitioners, could not afford a consultant's fee. Any registered medical practitioner would be allowed to bring to the out-patient department patients under his own care for consultation with members of the honorary medical staff. The actual attendance of the practitioner at such consultations would be eminently desirable and written statements would only be received in exceptional cases. No treatment would be given at the hospital in these cases, but the diagnosis made and the treatment advised would be communicated to the practitioner. The question of charging a fee for such consultations had been considered and the committee were in favour of a small payment. Mr. Dent pointed out that the scheme was only experimental.

Mr. Dent's description of the proposed arrangements in connexion with the new Belgrave Hospital was followed by a short paper entitled Suggestions for the Reform of Casualty and Out-patient Departments, contributed by Mr. W. H. KESTEVEN. It was admitted that the number of cases attending the casualty departments had increased of late years with excessive rapidity, while there had also been an increase of out-patients, and that many cases in both departments were of a trivial character which could be dealt with satisfactorily by general practitioners and for which hospital aid was unnecessary. The practical suggestions which he submitted as the result of conference with others were that all casualty cases should be seen by a medical officer, who should select from them cases which were urgent or of value for educational purposes, referring the rest in general terms to local medical men or an approved provident dispensary. In the out-patient department also the selection was to be made by a medical officer, but the suggestions for disposing of them were more complicated, including a limitation of the number of new cases to 15 or 20, a preference for members of friendly societies, provident dispensaries, and others recommended by their own medical attendants, and the reference of destitute cases to the Poor-law. The suggestions also included the employment of a trained almoner to make inquiries. Mr. Kesteven suggested the advisability of hospitals ceasing to provide drugs and giving prescriptions instead; this would bring the expenditure of hospitals within their means and would secure more experienced treatment for the sick poor who had to resort to them.

A discussion followed in which several medical men took part.

Mr. GARRETT HORDER congratulated the Charity Organisation Society on having secured two such practical papers after years of talk. He questioned the wisdom of Mr. Kesteven's suggestion that prescriptions should be given instead of medicines and he referred to the successful working of admission committees at Oldham and Dorchester. It seemed to him to be a suitable plan for small hospitals.

Mr. NELSON HARDY welcomed the Belgrave Hospital scheme as the first serious attempt on behalf of an established institution to deal with a problem which had been agitated for thirty years and more.

Dr. WARING (Brighton) gave some figures, which have already appeared in THE LANCET, showing that over a quarter of the inhabitants of Brighton and Hove appear to have been in receipt of hospital relief in 1896. He also stated that in a recent year no less than one-third of the births had taken place in the West-street Lying-in Hospital.

Other speakers took part in the discussion, and after brief replies from Mr. DENT and Mr. KESTEVEN the meeting closed with a vote of thanks to Sir Joshua Fitch for presiding.

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

THE twenty-seventh sitting of the Royal Commissioners was held at the Guildhall, Westminster, on Monday, June 27th. With the exception of Mr. Cripps, Q.C., all the Commissioners were present. The first part of the sitting was occupied by hearing the evidence of Mr. James Bigwood, M.P., the Chairman of the Parliamentary Committee of the Middlesex County Council, and Member of Parliament for the Brentford Division of Middlesex. The latter part of the sitting was occupied in hearing the evidence of Mr. E. J. Halsey, the Chairman of the Surrey County Council.

Mr. BIGWOOD, in answer to the CHAIRMAN, said that the area over which the Middlesex County Council had jurisdiction was partly within the limits of supply of the New River, the West Middlesex, the Grand Junction, and the East London water companies, and that the most thickly populated part of Middlesex, which was close to the boundary of London, was supplied by the three first-mentioned companies. The actual sources of the water were situated in the county and in the opinion of the witness Middlesex had a claim to the water found in the county. A large quantity is obtained in Middlesex by the New River Company at White Webbs, Highfield, Campsbourne, and Bettstile wells, situated respectively at Enfield, Edmonton, Hornsey, and New Southgate. During the last twenty-five years the population of Middlesex has practically doubled. The people of Middlesex wish to be a separate body, independent of London both as regards rating and in every other respect, and the Middlesex County

Digitized by Google

Council had petitioned against the various water Bills which had been promoted from time to time since the year 1891 by the metropolitan water companies and also against the transfer and purchase Bills which had been introduced by the London County Council. The position which the people of Middlesex took up with regard to the water-supply might be briefly summarised as follows:—1. That no scheme would be acceptable to Middlesex which did not provide for no further water being abstracted from the Middlesex water-supply. 2. Which did not give independent control from the beginning to Middlesex (*a*) of their sources of supply; (*b*) of their service. 3. Absolute non-interference with Middlesex either as to rating or otherwise. The witness thought that although it might possibly be advantageous in some provincial towns that the management of the water should be under the local authorities, it did not follow that that would be the best course in such an area as "Water London," which included not only the metropolis, with a population of nearly 4,500,000, but also the outside population of "Greater London," which in 1891 amounted to 1,401,688; and the outlying parts of "Water London," which in 1891 amounted to 76,041. Should it be thought that the water for Metropolitan London would be best managed by one authority it did not follow that the London County Council should be the authority entrusted with that management. In the opinion of the witness the London County Council had not time to devote to the matter and, moreover, the water-supply should not be managed by an elected body. It was his opinion also that there was plenty of water to supply the wants of Middlesex in the soil of the county and in the Thames.

In answer to Mr. MELLOR the witness said that he himself had dug a well and found an abundant supply of water. The Parliamentary Committee of the Middlesex County Council in the year 1891 formulated their views on what the necessities of the county required in connexion with the question of the water-supply. The resolution was as follows:—

1. That the interests of the county require that in any dealing with the question of the London water-supply, as it affects Middlesex, provision should be made against (*a*) the sinking of any new wells in the county, (*b*) the deepening of any existing wells in the county, (*c*) for limiting the abstraction of water for the London or any other external supply from Middlesex.

2. That no scheme will be acceptable to Middlesex which does not provide (*a*) for no further water being abstracted from the Middlesex area; (*b*) for the independent control (from the beginning) of (1) the source of supply, (2) the supply service; (*c*) for the absolute non-interference with Middlesex, either as to rating or otherwise.

The Middlesex County Council thought that it would be distinctly against their interest that any outside authority should acquire the powers of any of the metropolitan companies with reference to the supply of water in the area which was under the jurisdiction of the Middlesex County Council and that no outside authority ought to be empowered to control or in any way interfere with their supply. The interests of such an outside authority as the London County Council might and probably would be antagonistic to those of the county of Middlesex. Briefly, Middlesex preferred that matters should remain as they are at present and strongly protested against being made a party to the scheme for bringing water from Wales. The Middlesex County Council had at present no jurisdiction over the water supplies and they appeared before the Commissioners to protect the interests of their county, and whilst they were willing that London should take any steps for itself, they on their part protested against the London County Council or any other body interfering in any way with the county of Middlesex. Should any outside authority have such power as the London County Council sought to obtain the results which might be expected would result in (1) Attempts to annex, thereby enormously increasing rates; (2) involving Middlesex in any new scheme which it does not want, and thereby saddling it with still vaster rates for no useful purpose, against its will; (3) compelling Middlesex to pay far more for its water than consumers in London do; and (4) compelling Middlesex to bear part of any burden cast upon Surrey or on South London in which Middlesex has no interest, for supplies which they may need but Middlesex does not.

The witness put in a table which showed that in many cases in which provincial towns supplied outlying districts more was charged for the water in those districts than in the town itself—for example, in the case of Ashton the outside consumers paid 25 per cent. more, and in the cases of Guildford, of Halifax, and of Burnley no less than 50 per cent. more than the inhabitants of those towns were called upon to pay. In the opinion of the witness the scheme for the purchase of the undertakings of the water companies should be rejected and additional powers of control over the present undertakings should be granted. The witness suggested that a Board of Control should be formed with a view to secure the following results:—

1. Sufficient supply to all consumers, whether within or without the county of London. 2. Efficient, and very stringent, methods of preventing waste. 3. The primary right of the inhabitants of any district, from which water is abstracted, to a sufficient supply to meet their requirements. 4. More economical administration of the companies' affairs. 5. The application of any dividends in excess of 10 per cent. on the paid-up capital of any company, to the reduction of water-rates. It might possibly be necessary to come to some arrangement with the companies, especially the Southwark and Vauxhall, and the New River Companies, as to their maximum dividend. 6. Easy and simple method, by application to a tribunal or officer, who can at once and without waste of time, settle questions in dispute between any company and any water consumer. This is partially met by the Metropolitan Water Act, 1897. 7. The right to make up back dividends to be restricted and to be extinguished by such a capital sum as is just in each case. 8. That the companies should be placed under regulations analogous to those under which the gas companies now carry on their undertakings.

The CHAIRMAN examined the witness in some detail with regard to the formation of a board of control and as to how the orders given by the board should be carried out, whether the board should have power to order fines and imprisonment, power, for example, to take a recalcitrant water company director and put him in prison. The witness replied that he had not worked out the details of the manner in which control should be exercised, but he insisted that there were at present matters which required control and he gave in detail the example of a firm of distillers on whom one of the water companies had served a long list of demands, some of which he thought frivolous and some ridiculous. One of these demands referred to the size of a cistern: the company had insisted that a three-gallon cistern should be substituted for a two-gallon one, and shortly afterwards that a two-gallon cistern should be substituted for the new one which had just been put in on their demand. The witness thought that the local authorities should not continue to have the power to alter the level of the public roads in such a way that the distance of the water mains below the surface of the road was lessened and the mains were therefore exposed to the danger of frost.

In answer to Mr. CRIPPS, the Parliamentary agent of the London County Council, who cross-examined in the absence of learned counsel, the witness said that the people of Middlesex objected to having their own water first taken from them without payment and then sold back to them again. In his opinion London was not at present adequately supplied with water. A sufficient amount, for example, was not used for cleansing the streets.

In answer to Lord ROBERT CECIL, who appeared on behalf of the Hertfordshire County Council, the witness said that his contention was that the underground water belonged to the county in which it was situated, and that Middlesex had a right to a share in the Thames. With regard to the metropolitan water companies he thought that some of them had harshly exercised their powers with regard to water fittings, and he thought they were wrong in insisting on payment for water which they did not supply in periods of drought.

Mr. E. J. HALSEY, Chairman of the Surrey County Council, gave evidence with regard to the attitude of that body. In May, 1895, the Surrey County Council had explained fully their views to the Local Government Board and had condensed their reasons for their opinion. The Council adhered to the views which they then expressed and which were briefly as follows: (1) They considered that the council of another county should not have any jurisdiction within the county of Surrey and (2) that by any future action of the London County Council no part of Surrey ought either directly or indirectly to be made liable for the cost of providing a fresh supply of water for London, which they apprehended might happen if the London County Council obtained any control, however slight, of the water-supply available for any part of Surrey.

In answer to Major-General SCOTT the witness said he understood that in the case of purchase the London County Council proposed that Surrey should at first have the amount of water from the Thames which they take at present plus 20 per cent., but if more water were wanted afterwards Surrey would certainly claim her share. Surrey had, however, supplies of her own from the chalk and from the lower greensand.

Digitized by Google

In answer to the CHAIRMAN the witness said that he could not imagine a Water Board so constituted that it would be a fair one. However "good and delightful" Welsh water might be Surrey did not want it.

In answer to Mr. DE BOCK PORTER the witness said that the Surrey County Council were not entirely satisfied with the present supply given by the metropolitan water companies; they had, however, at present not had sufficient time to see the effects of the Act of 1897.

In answer to Major-General SCOTT the witness said that for his part he did not very much admire that Act, the machinery he thought was too cumbrous and too expensive. It would be better if a department were created at the Local Government Board or the Board of Trade to which application could be made in case of complaint. A department so created would be absolutely impartial and judicial, and small matters could be much better rectified in that way by a less formal and more friendly appeal than by a process of law. Complaints had lately been made at Kingston with regard to the hours at which the supply was given. It was thought that there might be a delay in getting water in case of a fire. The witness was strongly of opinion that the purchase of the metropolitan water companies' undertakings would not be a good thing, but if purchase were carried each county should undoubtedly have entire control of its own supply.

In answer to Mr. PEMBER, who appeared for some of the metropolitan water companies, the witness insisted that the Kingston people had a distinct grievance in not having had a constant supply of water.

In answer to Lord ROBERT CECIL, the witness said that should it be found necessary to exercise any new form of control it would be most easily and efficiently carried out by a special department under the Local Government Board.

In answer to Mr. CRIPPS, the witness said that the purchase and management of the metropolitan water companies' undertakings by the London County Council would be the worst possible arrangement that could be arrived at.

At the conclusion of the sitting the chairman announced that two sittings would be held next week and that the Commissioners proposed in future to sit regularly twice a week.

THE PRESS BAZAAR.

HER ROYAL HIGHNESS THE PRINCESS OF WALES, accompanied by Her Royal Highness the Duchess of York, arrived punctually at half-past two on Tuesday afternoon last at the Hotel Cecil to open the Press Bazaar in aid of the London Hospital. The Royal party were received by the Hon. Sydney Holland, chairman of the London Hospital, Viscount Knutsford, Lord Tweedmouth, and Mrs. J. A. Spender, honorary secretary of the Bazaar.

"From the entrance the Royal party were conducted to the Oak Room, where the Bazaar Committee were presented to Her Royal Highness.

"The Dowager Countess of Shrewsbury as editor in chief of the *Press Bazaar News* welcomed Her Royal Highness's visit to our office.

"The managing editor was then introduced and Her Royal Highness expressing an anxiety to learn something about the linotype machine Mr. Joseph Lawrence, the chairman, explained the mechanism.

"Special bars were struck commemorative of the Royal visit and handed to their Royal Highnesses."

This is the account of the opening as reported in the *Press Bazaar News*, the official organ of the Bazaar, and our apology for giving it in our contemporary's words instead of devoting some columns to describing the highly interesting scene in our own language must be that no great facility was given to the press for seeing or learning what was going on.

With the exception of absence of provision for the press the Bazaar must be pronounced a decided success, for in no sense can overcrowding be looked upon as other than a virtue at such a function. On both days the rooms devoted to the Bazaar and the approaches to the hotel were thronged with fashionable London, and the display of millinery in the carriages which blocked the Strand during the afternoon of Tuesday was a thing to be seen to be believed in. The newspapers represented at the stalls were: *Queen*, *Referee*, *Weekly Dispatch*, *Stage*, *Sun*, *Tablet*, *Vanity Fair*, *Truth*, *Westminster Gazette*, *World of Dress*, *Illustrated London News*, *Sketch*, *Lady's Pictorial*, *Jewish Chronicle*, *The Lady*, *Morning Post*, *Ladies' Field*, *Strand Magazine*, *Country Life*, *Daily Mail*, *Evening News*, *Naval and Military Magazine*, *Observer*, *Sunday Times*, *Punch*, *Artist*, *Black and White*, *Daily Chronicle*, *Hospital*, *Financial News*, *Gentlewoman*, and *Graphic*.

We cannot attempt to enumerate either the articles for sale or the names of the benevolent ladies who gave their time and energy to selling them, but our readers will have seen full reports of these matters in the daily press. The wares ranged from dairy produce to jewels and from strawberries and cream to monkeys on sticks, and the wives and daughters of the peerage and of editors and proprietors of journals assisted lady-journalists and the aristocracy of the stage to dispense them. Perhaps the most practical stall was that of the London Hospital, presided over by the sisters in their pretty pale-blue dresses. Here clothing of all kinds for charitable purposes could be bought and not a few of the visitors returned their purchases to the Sisters in order that the garments might be given to the patients in the wards of the hospital. The Princess of Wales and the Duchess of York made several purchases at this stall, as they did also at many of the other stalls.

Quite a novel feature of the Bazaar was the issue of the daily paper from which we have already quoted. The *Press Bazaar News*, described as the "dearest little paper in the world," the price being 1*s*. per copy, was a four-page paper with four columns to a page and its entire production was carried out in the Oak Room of the Hotel Cecil. Mr. F. C. Gould drew for its pages three political cartoons in his well-known style. They represent Mr. Joseph Chamberlain, Lord Salisbury, and Sir William Harcourt as visitors to the bazaar with their purchases. Mr. Chamberlain has bought a bust of Kruger, some long spoons, and a case of Russian caviare, and Lord Salisbury has indulged in the luxury of a Dutch clock (with pendulum) and a china vase. The best satire of all is the representation of Sir William Harcourt with Foxe's Book of Martyrs under one arm and a censer in the disengaged hand. Mr. Henry Irving as dramatic critic contributed an amusing account of a recitation entitled "Gemini et Virgo." In connexion with the issue of the paper the press museum formed a feature which attracted many of the visitors.

It remains to be added that some of the most eminent actors and actresses in London contributed to the dramatic and musical entertainments which were provided by the management.

The exact sum which will be received by the London Hospital as the result of the Bazaar has not been announced as we go to press. That the sum will be over £10,000 seems certain, which alone constitutes, we believe, a record, but the takings at several of the stalls have not yet been sent in to the honorary secretary. We have to congratulate Mrs. Spender on the splendid result of her idea. That she has received hearty and influential coöperation is certain; but the Bazaar was initiated by her and the hard work of turning an idea into a going concern was borne wholly by her, and she deserves the hearty thanks of the great charity for the funds of which she has done such a splendid stroke of business. We, in common with many other journals, and perhaps with even more obvious reason, were unable to be practically associated with a bazaar having for its object the relief of one particular London hospital, but this does not prevent us from sympathising with the work and rejoicing at its success.

THE BATTLE OF THE CLUBS.

NOTTINGHAM MEDICAL UNION.

THE annual report of the Council of this Union was adopted at the general meeting on June 1st. In December, 1897, the following important circular was issued to all the members:—

Recent legislation with regard to friendly societies has legalised the admission of juvenile members to adult lodges and members of the Union have been approached on the subject of admitting such juvenile members at rates of payment differing from those of adults.

Under these circumstances the Council of the Union think it desirable

Digitized by Google

to remind members that the agreement of Oct. 7th, 1896—"I hereby undertake after Jan. 1st, 1897, not to enter into any new club or contract engagement for less than 4s. per year per member"—applies to juvenile as well as to adult members.

Reports were made to the last meeting of the Council of flagrant instances in which patients of members had been canvassed by agents of one of the medical aid associations, and it is suggested that the promises made a little more than a year ago have not been kept; but the Council have not seen their way to advise any more active policy as regards the medical aid associations this year than last and for the same reason; active opposition cannot be successfully pursued until we have complete unanimity and present an unbroken front.

A few months ago there was a conference in London between representatives of the British Medical Association and some of the friendly societies. It was very amicable and the representatives of the friendly societies seemed anxious to look at all sides of the question and to consider a revision of scales. By quiet work it will gradually be made plain that the club rates must be revised sooner or later.

The question of hospital abuse has not been forgotten. There have been several meetings of the committee involving a great deal of work. A joint meeting with a committee of the monthly board of the General Hospital has been held. Work of this kind is very slow but it has been continuous.

The treasurer reports that the funds of the union are in a satisfactory state.

THE ANCIENT ORDER OF FORESTERS AT EVESHAM.

Court No. 4648, Vale of Evesham of the above friendly society is in a parlous condition as regards medical aid. On June 7th a specially summoned meeting of the court was held to consider a proposal to reduce the salaries of the medical officers, Mr. A. H. Martin and Mr. J. S. Slater, who have held the appointment for the last twenty-five years, from 5s. per member per annum to 4s. The only notice given had been by means of the agenda paper which was dropped into Mr. Martin's letter-box about a week previously to the meeting. Under the rules of the society the surgeons only hold office "according to the pleasure of the court." Mr. Martin attended the meeting on June 7th and before the resolution was put explained that if it were carried he and his partner would immediately resign. It was carried and both medical officers at once sent in their resignations, which were accepted by the court, which thereupon carried a resolution that they should advertise for another medical officer at the rate of 4s. per member per annum. All the other medical men residing in Evesham have been applied to but all refuse to have anything to do with the society at the reduced rates. The club is therefore now without any recognised medical man and the secretary has instructed any members who are ill to go to what medical man they like and then send in the bills to him. The committee of the court have refused to pay Mr. Martin and Mr. Slater the salary due to them on June 7th—i.e., one quarter's salary—and these gentlemen have therefore issued a county-court summons to obtain their due. So matters stand at present and we congratulate the medical men of Evesham upon their firm stand. We will only add that if Mr. G. Carrick, the secretary of the court, likes to send us his official account of what has happened and what is going to happen we shall be happy to comment fully on, or possibly print, it.

EAST SUBURBAN MEDICAL PROTECTION AND MEDICO-ETHICAL SOCIETY, LIMITED, WEST HAM HOSPITAL, E.

The first statutory meeting of the above society was held at the West Ham Hospital on June 23rd, 1898. There was a large and widely representative gathering of practitioners from the neighbouring districts, including some lady practitioners. Over thirty new members were elected at the meeting. The Executive Council was elected for the ensuing year. The President, Dr. F. J. Smith, delivered his address on the Aims and Objects of the Society. These were practically explained at the inaugural meeting of the society, a full report of which was published in THE LANCET of Feb. 12th, 1898, p. 459. The secretary, in answer to inquiries, explained that the scheme for the formation of local branches was under consideration; it was certainly desirable to have local representatives who should be elected as far as practicable by the local men. The secretary also said that a scheme for keeping a black list had been prepared for consideration by the council, that arrangements had been made to commence the debt-collecting at an early date and that the views of individual members would be represented by the fact that the whole council was elected annually.

It was resolved that a general meeting should be held quarterly to receive report of work done by the council.

It was stated that clinical and social meetings would be held as soon as possible and as often as desired by members.

The date of the next council meeting was fixed for Thursday, July 14th.

The headquarters of the society are at the West Ham Hospital, Stratford, E., and the hon. secretary is Mr. Murtaugh Houghton. The society is only in its youth, but there can be no doubt of the necessity for its existence, and the fact of thirty new members joining at the first statutory meeting is of good augury for its prosperity.

BRITISH INSTITUTE OF PREVENTIVE MEDICINE.

THE annual general meeting of the British Institute of Preventive Medicine was held on June 24th at Chelsea, among those present being the Duke of Westminster, the Earl of Feversham, Lord Lister, Dr. Pye-Smith, Dr. Thomas Bridgwater, and others. The chairman submitted the annual report of the council, which was adopted.

The report stated that during the year the work of the Institute has been marked by progression and expansion. The internal fittings of the new building are in an advanced state, some departments are already in full working order, and it is confidently anticipated that all will be fully equipped in the early autumn. The Institute has published during the year a volume of Transactions, which has been favourably received. The demand for diphtheria and streptococcic serum has increased and there has also been an increased demand for mallein and tuberculin. The Institute has rented laboratory accommodation to the Local Government Board for the purpose of preparing glycerinated calf lymph. It was also stated that the Institute would require a considerable addition to its funds to enable it to carry out adequately the objects for which it was founded.

The report of the hon. treasurer, Sir Henry E. Roscoe, containing the balance-sheet and statement of accounts duly audited, was submitted to the meeting and adopted. The directors' report and the reports of the scientific staff were also adopted and it was directed that these should be circulated amongst the members of the institute.

Dr. Horace Brown, F.R.S., was elected a member of council in place of the late Surgeon-General W. R. Cornish.

The volume of Transactions, published by Messrs. Macmillan and Co. on behalf of the Institute, contained nine original contributions by members of the staff. A review of this volume appeared in THE LANCET of Jan. 8th, 1898, p. 106. A number of fresh investigations have been conducted and completed during the year, some of which are published and others are on the eve of publication. There are also other investigations in progress and the laboratories continue to attract research workers. The courses of instruction given by the staff have also been well attended. About 2000 reports were sent out by the Institute during the year.

The Institute has endeavoured to encourage the periodical examination of water and water-supplies and several local authorities have requested the Institute to undertake this systematic examination on their behalf. Bacteriological work has also been undertaken for several additional sanitary authorities. In the new building every facility is being provided for the furtherance of bacteriological research and the antitoxin department at Sudbury continues to do useful work in the field of serum therapeutics.

At the close of the meeting the members inspected the fittings of the new laboratories which will be formally opened in the autumn.

THE ROYAL EYE HOSPITAL, SOUTHWARK.—A festival dinner of this institution was held at the Hôtel Métropole on June 17th. The chairman said the hospital ministered to the needs of a population of nearly a million and three-quarters and last year had relieved 15,400 out-patients and over 400 in-patients, 30 per cent. of whom were under twenty years of age and about 16 per cent. under thirteen years of age. A large number of the community were thus saved from blindness and a life of comparative inutility. In the course of the evening a record sum of £2170 was announced by the secretary as the result of the dinner.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On an outbreak of enteric fever in the Urban District of Camborne and in portions of the adjoining Rural Districts of Redruth and Helston, by Dr. R. BRUCE LOW.[1]—A sudden outbreak of enteric fever appeared in December, 1897, at Camborne, in Cornwall, a town with some 14,000 inhabitants. Simultaneously excessive prevalence of enteric fever was manifest in two rural parishes which adjoin Camborne. Altogether 165 cases, 12 of which proved fatal, were notified from these places in the course of six weeks. No doubt, Dr. Bruce Low points out, a considerable number of other cases occurred which did not come to the knowledge of the sanitary authorities concerned. The facts which Dr. Low records leave no room for doubt that the cause of this epidemic was a specifically infected public water-supply. In Camborne and its neighbourhood there are, it is true, numerous insanitary dwellings and nuisances arising from accumulation of excrement and refuse abound in certain localities. But there had been no exceptional incidence of enteric fever upon the occupants of such unhealthy dwellings and localities. And, as Dr. Low shows, the outbreak by its suddenness differed totally from what might have been expected had the epidemic been produced by excremental contamination of soil. The question of infected milk could at once be set aside. But as regards water the case was otherwise. The Camborne Waterworks Company supplies with water the greater number of houses in Camborne and also a few small areas in the adjoining rural parishes of Illogan and Crowan. Dr. Bruce Low gives the following table showing the incidence of the disease upon houses supplied and upon houses not supplied by this public service:—

Localities invaded by enteric fever during December, 1897, and January, 1898.	Houses supplied by the Camborne Company.			Houses not supplied by the Camborne Company.		
	Number of houses supplied.	Invaded by fever.	Per cent. invaded by fever.	Number of houses not supplied.	Invaded by fever.	Per cent. invaded by fever.
Camborne Urban District...	2365	106	4·5	762	5	0·7
Illogan parish	810	26	3·2	1297	2	0·2
Crowan parish	158	7	4·4	427	2	0·5
Total	3333	139	4·2	2486	9	0·4

Persons attacked in the 9 dwellings not included in the area of public supply had in several instances consumed the Camborne Company's water shortly antecedently to illness. Indeed, of the total of 165 cases there were practically only 2 attacks in which there was doubt as to the persons having had opportunities of drinking water from the incriminated supply. The conditions under which water was obtained by the Camborne Water Company can hardly be considered other than scandalous. Two gathering grounds contribute to their supply. Water from the first at Cargenwyn is commonly used in the summer months only. It had been cut off four weeks or more antecedent to the beginning of the epidemic and could not therefore be considered to have had to do with the causation of the outbreak. Incidentally, however, we note that part of this Cargenwyn supply was found by Dr. Low to consist of the natural drainage of fields, upon several of which human excrement was scattered. This is hardly to be wondered at when we learn that of 19 dwellings upon this gathering ground 13 had no privy or closet accommodation

[1] London: Eyre and Spottiswoode, East Harding-street, E.C.; Edinburgh: John Menzies and Co.; Dublin: Hodges, Figgis, and Co. 1898. Price 7d.

Digitized by Google

whatever. The gathering ground which alone furnished the water supplied by the company immediately prior to and during the outbreak was that at Boswyn. Here the main source of supply is a series of springs, water from which is received in a service tank. But in addition water from a brook in the neighbourhood was conveyed to this tank by pipes. In dry weather this brook receives little pollution, but in rainy weather surface pollutions are washed into it by storm-water. Pollution of surface more especially occurs in connexion with 9 houses on the watershed area. None of these houses have any suitable drainage arrangements and six have no closet or privy of any kind. Now, in October and November 4 cases of enteric fever had occurred in one of these houses. During this time slops and liquid refuse were thrown into a small pond close by the house. There being no privy, excrement was thrown in the neighbourhood of the house on to the surface of ground which drains to the same pond. In dry weather this pond had no overflow, but in times of rainfall the pond water escaped by a small watercourse directly into the brook which fed the service reservoir. Now, the epidemic first became known by the notification of 62 cases of enteric fever between Dec. 4th and Dec. 18th, and on Nov. 12th and 13th there had been an exceptionally heavy rainfall over Boswyn gathering ground. About this date the pond, no doubt highly contaminated with infectious matter, became full and there can be no question that its overflow made its way, as usual, straight to the brook and so to the service reservoir. The water of this reservoir was delivered to consumers without filtration. The outbreak came suddenly to an end after the brook water was shut off from the service tank and after the latter had been scrubbed out and the water-mains had been well flushed.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6173 births and 3247 deaths were registered during the week ending June 25th. The annual rate of mortality in these towns, which had been 16·9 and 14·7 per 1000 in the two preceding weeks, rose again last week to 15·1. In London the rate was 14·5 per 1000, while it averaged 15·5 in the thirty-two provincial towns. The lowest rates in these towns were 9·6 in West Ham, 10·3 in Norwich, 10·9 in Croydon, and 11·1 in Brighton; the highest rates were 19·9 in Manchester, 20·0 in Plymouth, 21·4 in Sunderland, and 24·3 in Newcastle-upon-Tyne. The 3247 deaths included 302 which were referred to the principal zymotic diseases, against 381 and 341 in the two preceding weeks; of these, 89 resulted from measles, 83 from whooping-cough, 61 from diarrhœa, 36 from diphtheria, 21 from scarlet fever, and 12 from "fever" (principally enteric). No death from any of these diseases was recorded last week in Nottingham; in the other towns they caused the lowest death-rates in Croydon, Brighton, and Blackburn, and the highest rates in Plymouth, Sheffield, Gateshead, and Newcastle-upon-Tyne. The greatest mortality from measles occurred in Halifax, Newcastle-upon-Tyne, and Plymouth; and from whooping-cough in Swansea and Sunderland. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 36 deaths from diphtheria included 21 in London, 4 in Birmingham, 2 in West Ham, 2 in Cardiff, and 2 in Manchester. No fatal case of small-pox was registered last week either in London or in any other of the thirty-three large towns; and no small-pox patients were under treatment in any of the Metropolitan Asylum Hospitals on Saturday last, June 25th. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on the same date was 2238, against 2169 and 2194 at the end of the two preceding weeks; 231 new cases were admitted during the week, against 220, 206, and 230 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 212 and 185 in the two preceding weeks, further declined to 171 last week, and were 38 below the corrected average. The causes of 32, or 1·0 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Manchester, Leeds, and in sixteen other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Leicester, Preston, and Bradford.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the three preceding weeks from 23·0 to 20·2 per 1000, further fell to 19·5 during the week ending June 25th, but exceeded by 4·4 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 16·7 in Aberdeen and 17·8 in Edinburgh to 24·5 in Leith and 25·5 in Perth. The 589 deaths in these eight towns included 37 which were referred to measles, 27 to whooping-cough, 26 to diarrhœa, 6 to scarlet fever, 4 to "fever," and 2 to diphtheria. In all, 102 deaths resulted from these principal zymotic diseases, against 116 and 92 in the two preceding weeks. These 102 deaths were equal to an annual rate of 3·4 per 1000, which was 2·0 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 42 and 32 in the two preceding weeks, rose again to 37 last week, and included 14 in Dundee, 13 in Glasgow, and 7 in Edinburgh. The deaths from whooping-cough, which had been 43 and 22 in the two preceding weeks, increased to 27 last week, of which 18 occurred in Glasgow. The 6 fatal cases of scarlet fever were within 2 of the number in the preceding week, and included 4 in Glasgow and 2 in Edinburgh. The deaths referred to different forms of "fever," which had been 8 in each of the two preceding weeks, declined to 4 last week, of which 3 occurred in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 109 and 108 in the two preceding weeks, further declined to 93 last week, and were 11 below the number in the corresponding period of last year. The causes of 27, or nearly 5 per cent., of the deaths in these eight towns were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 25·1 and 21·9 per 1000 in the two preceding weeks, rose again to 22·8 during the week ending June 25th. During the past four weeks the death-rate in the city has averaged 22·4 per 1000, the rate during the same period being 15·2 in London and 20·5 in Edinburgh. The 153 deaths registered in Dublin during the week under notice showed an increase of 6 upon the number in the preceding week, and included 8 which were referred to the principal zymotic diseases, against 4 and 6 in the two preceding weeks; of these, 5 resulted from whooping-cough, 2 from diphtheria, and 1 from diarrhœa, but not one from small-pox, measles, scarlet fever, or "fever." These 8 deaths were equal to an annual rate of 1·2 per 1000, the zymotic death-rate during the same period being 1·5 in London and 2·5 in Edinburgh. The fatal cases of whooping-cough, which had declined from 5 to 1 in the three preceding weeks, rose again to 5 last week. The two deaths referred to diphtheria exceeded the number recorded in any recent week. The 153 deaths in Dublin last week included 23 of infants under one year of age, and 55 of persons aged upwards of sixty years; the deaths of infants showed a decline, while those of elderly persons exceeded the number in any recent week. Seven inquest cases and 5 deaths from violence were registered; and 51, or one-third, of the deaths occurred in public institutions. The causes of 10, or nearly 5 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

THE NEW ARMY MEDICAL WARRANT.

IT probably did not escape our readers' attention that Mr. Powell Williams stated in the House of Commons on Monday last, the 27th ult., that the warrant constituting the new Royal Army Medical Corps had been approved by Her Majesty and will be published in the Army Orders for this month.

ARMY MEDICAL STAFF.

Brigade-Surgeon-Lieutenant-Colonel Joseph H. Moore to be Surgeon-Colonel, vice W. Graves, retired. Surgeon-Lieutenant-Colonel James Tidbury retires on retired pay.

Digitized by Google

INDIA AND THE INDIAN MEDICAL SERVICES.

To be Surgeon-Colonel: Brigade-Surgeon-Lieutenant-Colonel Thomas Holbein Hendley, C.I.E., Bengal Establishment. Surgeon-Majors to be Surgeon-Lieutenant-Colonels: *Bengal Establishment:* Jarlath J. Ffrench Mullen, Eugene Cretin, Andrew Duncan, George Frederick Nicholson, Samuel Ferguson Bigger, and Sir George Scott-Robertson, K.C.S.I. *Madras Establishment:* Thomas Henry Pope, Robert Pemberton, Damodar Purshotam Warliker, James Joseph Moran, William Adair Quayle, and Henry Armstrong. *Bombay Establishment:* Charles Monks, Phirozsha Jamsetjee Damania, George Henry Bull, and Frederick Fitzgerald MacCartie, C.I.E. Surgeon-Captains to be Surgeon-Majors:—*Bengal Establishment:* William Grant Thorold, Patrick Hehir, Lionel John Pisani, Basanta Kumar Basu, Narendra Prasanna Sinha, William Rice Edwards, Charles Mactaggart, John Fenton Evans, George James Hamilton Bell, Joseph Thomas Daly, Henry Fooks, Ernest Hudson, Arthur William Dawson, and William Henry Banner Robinson.

The Queen has also approved of the retirement from the service of the undermentioned officers: Surgeon-Colonel Samuel Bradshaw Hunt, Madras Establishment; Brigade-Surgeon-Lieutenant-Colonel James Arnott, Bombay Establishment; Surgeon-Lieutenant-Colonel James Moorhead, Bengal Establishment; and Surgeon-Lieutenant-Colonel James Charles Harding Peacocke, Bombay Establishment.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain J. H. Anderson, to be Surgeon-Major.

VOLUNTEER CORPS.

Rifle: 1st Volunteer Battalion the Buffs (East Kent Regiment): Surgeon-Captain R. Bevan resigns his commission. 2nd Volunteer Battalion the Royal Sussex Regiment: Surgeon-Lieutenant A. W. W. Caudle resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the battalion on his retirement.

THE SPANISH-AMERICAN WAR.

The most serious news from a medical standpoint at the present moment is the alleged outbreak of yellow fever among the American troops. The situation of the belligerents has of late become more acute and is at the present time interesting, but as bewildering as ever. The war policy of Spain, as regards her naval forces, baffles the understanding. With one—and the main—portion of her fleet shut up and powerless at Santiago the reason for sending the other portion from Cadiz to the Suez Canal (where it cannot coal), probably for somewhere in the Philippines, is not very obvious, for it cannot reach its destination in time to be of any service as far as Manila is concerned, and Admiral Dewey's squadron there is strong enough to defeat it if it does. It is quite possible that the object of the Spanish Government is simply to put Admiral Camara's fleet in a safe place on this or the other side of Suez. The interest of the situation at Manila is just now connected with the policy of the Germans in that quarter. Meanwhile the Americans are about to send some of their war-vessels into Spanish waters to threaten and bombard Spanish ports and then to follow up and engage Admiral Camara's fleet. An American force has invaded Cuba and had two sharp fights with the Spaniards, and this force is to be followed up by a much larger one for the capture of Santiago. In the small engagements the Americans lost an officer and 11 troopers, while some 50 men, including 6 officers, were wounded and are lying in the field hospital near Juragua. The American troops are about three miles from Santiago, where the Spaniards are strongly entrenched, and severe fighting may be shortly expected. It may prove a serious undertaking to drive the Spanish troops out of their entrenchments. Santiago and its vicinity will be strongly bombarded by the States war vessels previously to an attack. The heat is very great and the uniform provided for the American troops has been found to be unsuitable and altogether too heavy for the Cuban climate. The situation of the garrison of Manila is bad. There is a good deal of sickness, 1000 sick and 200 wounded being in the Spanish military hospitals. The heavy rains have increased the difficulty of holding the outworks and trenches.

RECRUITING.

It is, of course, too early to form any judgment as to what effect the new and more advantageous regulations will have upon recruiting for the army, but we confess to having some misgivings on the point. There can be no doubt that the soldier of the present day is very well off compared with what he was: he is better fed, lodged, clothed, and looked after and, considering the class from which he is commonly drawn, he is fairly well paid and he gets his money with the regularity of clockwork if he has not always so much of it at his disposal as in civil life. It is not the dislike of fighting or adventure which keeps young fellows out of the army, for a war quickens recruiting. It is the dislike of the discipline and routine of barrack life, the curtailment of liberty and loss of independence, together with the prejudice against the army as an occupation so frequently entertained on the part of the relatives and friends of the would-be soldier which deter them from enlisting. With the spread of education and the increase of intelligence it is not likely that this dislike to the restraints of military life will grow less. The army will have to move with the times. Discipline there must be if an army is to be kept efficient as a fighting machine. The point to be determined, however, is the nature and amount of it essential for the purpose and the extent to which petty and irksome restraints and interference with the soldier's liberty and independence can be removed or lessened without injury to the disciplinary spirit.

DEATHS IN THE SERVICES.

Brigade-Surgeon-Lieutenant-Colonel William Alexander Barren, I.M.S., Bombay Sappers and Miners, on June 8th, in his forty-ninth year. He entered the service in 1874 and served in the Afghan War of 1880 in medical charge of the 4th Bombay Infantry (medal); he also served in the Burmese expedition of 1886–88 (medal with two clasps).

Surgeon-General William Henry Adley, I.M.S., of Cleddy Lodge, Haverfordwest, on June 18th, aged seventy years.

Surgeon-General Frederick Morrison Clifford, I.M.S., Bengal (retired), on June 15th.

Surgeon-Lieutenant-Colonel Breame Weston Fowler, A.M.S. (retired), at St. Helena, in his forty-seventh year. He entered the army in 1873, was promoted to Surgeon-Major in 1885, and to Surgeon-Lieutenant-Colonel in 1893.

Surgeon-General J. C. Morice, I.M.S. (retired), on June 24th, aged sixty-one years. He entered the army in 1856 and served in the Indian Mutiny Campaign (medal with two clasps). In 1868 he served in the Hazara Campaign and took part in the operations on the Black Mountains (medal with clasp). In the Expedition of 1885 to Suakin he was mentioned in despatches (medal with clasp and bronze star).

GOOD SERVICE PENSION.

We have to congratulate Surgeon-General Alexander Smith, M.D. Edin., C.B., honorary physician to the Queen, on the fact that a good service pension of £100 per annum has been awarded to him. He entered the medical service in 1846 and retired from it in 1884. Surgeon-General Alexander Smith took part in three campaigns—namely, in the Crimea at the siege of Sebastopol and the attack on the Redan on June 18th, 1855, in the Jowaki expedition of 1877–78, and in the Afghan war of 1878–79–80 (as Principal Medical Officer of Sir Donald Stewart's force) at the actions of Ahmed Khel and Urzoo, on which occasion he was mentioned in despatches and was created C.B. He received medals and clasps for the foregoing campaigns and was appointed honorary physician to the Queen in 1894.

THE EXPEDITION TO KHARTOUM.

We understand that Surgeon-Major-General Taylor is to go as the principal medical officer of the Expeditionary Anglo-Egyptian force when the advance on Khartoum takes place. He has the reputation of being a good organiser and a clear-headed, energetic man of business. We congratulate him on his appointment to the post and on his good fortune. We understand that some 260 sick and wounded have come down to Cairo from the front and it is possible that they may be followed by about the same number before the advance takes place.

MEDICAL MAGISTRATES.—Mr. Marsham A'B. McCarthy, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., of Summer Hill, near Sydney, New South Wales, has been appointed a magistrate for New South Wales. Mr. George M. Anderson, M.B., Ch.M. Aberd., of Franklin, Tasmania, and Mr. P. J. A. Rockett, M.B., Ch.B. Melb., of Derby, Tasmania, have been appointed magistrates for Tasmania.

"Audi alteram partem."

"THE STATISTICS OF DEATH IN CHILD-BIRTH."

To the Editors of THE LANCET.

SIRS,—Mr. T. A. Coghlan's paper, read before the Royal Statistical Society on June 21st and briefly reported in your issue of June 25th, is worthy of the fuller notice of those who are interested in vital statistics and of those also who are concerned with the problems of child-birth. The paper is a report by the Government Statistician for New South Wales of an investigation into the births (query, rather confinements—the two are not distinguished as they should be in the paper), 115,669 in number, which had occurred in that colony during the three years 1894-96, and the deaths of mothers at child-birth, numbering 813 in all. Of the entire number of births, 9920, or 8·6 per cent., were illegitimate (with 99 deaths), a proportion which may be compared with that of 4·2 in England and Wales (1895), where we have witnessed a steady decline since 1850, when the proportion was 7 per cent.

The mortality of all the mothers amounted, it will be seen, to 7·0 per 1000 births; the married showing 6·7 and the unmarried 10·0 respectively, a higher death-rate for the latter which is to be expected, and which would perhaps have been still higher but that the bulk of such labours occur "in public institutions, which make the treatment of child-bearing women a special feature of their work." Some correction may be needed for multiple births, and still-births if registered.

We may compare these rates with that of 4·72 per 1000 births, which was the mean puerperal death-rate for England and Wales during the 30 years 1861 to 1890 (one mother dying out of 212 births). The difference is not very great and may perhaps be partly explained by the less accessible medical and other help at confinements in a colony where the population is widely scattered.

Mrs. Garrett-Anderson, who was present at the discussion, stated her belief that of late years in this country, since the adoption of antiseptic midwifery, the number of deaths in childbirth had greatly lessened. I fear that there is as yet no evidence of this very desirable result, however much we may hope for it in the future. The Registrar-General's returns show a fluctuating mortality from year to year, but on the whole very little improvement can be claimed. In 1895, the last year for which abstracts have been published, there was a death-rate from puerperal causes of 4·57 per 1000 births. But in 1893 it had been 6·51. Considering, however, the greater accuracy of the returns during recent years it is probable that the actual fatality is rather less than it was. Dr. Boxall,[1] Dr. W. Williams,[2] and Dr. Cullingworth[3] have fully illustrated this subject in your columns, and the first-named has shown that there is more evidence of lowering of the death-rate in London than in the provinces.[4] But the chief value of Mr. Coghlan's paper lies in his investigations into the effect of the number of the confinements and the age of the mother upon the mortality. This is a subject to which, it will be remembered, the late Dr. Matthews Duncan devoted much labour. He found it very hard to get data, and those which he obtained dealt with small numbers only. In his work, "Fecundity, Fertility, and Sterility," published in 1866, he has recorded all the observations he could find, and has drawn certain conclusions from them. Mr. Coghlan's data, although still on a small scale, are much larger than any in Dr. Duncan's possession; and, indeed, so far as I am aware, than any that existed. So that this paper is one of great importance in its own line of study, and cannot fail to be often referred to in the future.

The first question Mr. Coghlan takes up is the risk to life at each confinement. His conclusions agree closely with those of Matthews Duncan. The risk at the first confinement is large, that at the following labours is much smaller, but it gradually rises again later on, until at about the ninth confinement it equals that which attends the first. Mr. Coghlan falls, as I think, into one error. The actual figures for the second labour are very low (they work out at 4·6 deaths per 1000 births, compared with 8·7 for the first labour), but in the necessary adjustment of small variations, and to form a "curve," he raises the figure, and makes the risk to fall gradually from the first confinement down to a minimum at the fourth. Now, Duncan's conclusions and his own unadjusted tables show that the risk drops suddenly from the first to the second and after that gradually rises through later labours. And it is reasonable that it should be so. At the first labour the woman's strength and fitness for parturition are tested and the presence of mechanical or other difficulties revealed. It is more tedious than later labours, the nervous distress is greater, and the majority of illegitimate births is included in the category of primiparæ. All these circumstances increase the danger to life at this labour, whilst the second and subsequent confinements occur only to those who have passed through this ordeal, whose fitness has been tested, and who have retained their health so as to become again fertile.

Mr. Coghlan's tables and diagrams on the risk at first confinements confirm Matthews Duncan's views entirely, and the same is the case with his observations on the effect of the age of the mother. The only difference is that he places the age of least risk at twenty-three years, whilst Duncan makes it twenty-five, both agreeing that the risk rises on moving from this age to either an earlier or a later period of life. The extent of the increased risk is well shown, especially as it affects the immature (before the age of twenty years) and the more elderly mothers (after that of thirty years). Women who begin to bear after thirty years of age experience a considerable mortality. Perhaps an earlier maturity of women in the Australian colonies may have some influence in fixing the age of least risk. It is a striking testimony to the judicial mind of the great Scottish observer, reasoning as he did from scanty data, that Mr. Coghlan should, as it would seem quite independently, for he never refers to Duncan, establish upon fuller data conclusions which are practically identical with his.

The latter part of the paper is occupied with a rather speculative investigation of the probability of a woman's surviving every confinement. The calculations on which this is based were much criticised in the discussion, and the results are certainly startling. It would occupy too much space to enter into them here.

Before leaving the subject may I express the hope that our own registration authorities will follow the lead of New South Wales by including in their schedules such particulars as would make an investigation of this kind possible? At the registration of a birth the number of the confinement and the ages of the father and mother might reasonably be required, and when a death is certified as from puerperal causes, or child-birth is mentioned on the certificate, the number of the confinement and the sex of the infant should be specified. Stillbirths should similarly be registered. One speaker in the discussion averred that there was a larger proportion of male births among the unmarried than among the married, and that the maternal mortality was greater in the case of male infants. The latter is very likely true, for male infants are larger than female, and their own death-rate in infancy is known to be remarkably higher than that of girls. But from this dark region of conjecture, based on scanty records, we should, if my proposal were adopted, emerge into the light of fact. We should soon obtain ample data for investigating the conditions of child-birth, and the bearing of paternal and maternal age and of the epochs of gestation upon the number, sex, and vitality of the infants, and upon the life of the mother and her after-fertility. It is not too much to hope for the discovery of new laws by which the process of reproduction is governed. Chance disappears from nature the more closely we can discern her ways.

I am, Sirs, yours faithfully,

Finsbury-square, June 25th, 1898. R. HINGSTON FOX.

[1] THE LANCET, July 1st, 1893.
[2] THE LANCET, April 18th, 1896.
[3] THE LANCET, March 6th, 1897.
[4] I find that in London in the first 24 weeks of 1898 the deaths from puerperal causes were only 174, against a corrected average for the past ten years of 240·5.

"ESTIMATES OF POPULATION."

To the Editors of THE LANCET.

SIRS,—Will you allow me to make a few comments upon the important leading article in THE LANCET of June 18th upon the subject of the estimate of the population of Liverpool?

Digitized by Google

Previous Census returns have shown that during the latter years of inter-censal periods grave errors in the estimates of populations of various cities have been made. With regard to Liverpool the error at the close of the last Census amounted to 100,000 persons—about 19 per cent. of the total population—an error great enough to vitiate the statistics published by the Registrar-General for several years preceding the Census. As you point out, Dr. Ogle, the late Superintendent of the Statistical Department, addressed a letter in 1885 to the town clerk upon the subject of the estimated population, but unfortunately data were not then available to test the trustworthiness of the estimate. That circumstance, however, can hardly be advanced as an argument for declining to consider evidence now available and which tends to show that the estimate of to-day is incorrect.

The Registrar-General estimates that since 1891 the population of Greater Liverpool has increased from 629,443 to 633,078, making a total increase of 3635. The reasons for believing that this estimate is too low may be summarised thus: Since the Census of 1891 the increase in the number of births over deaths amounts to 39,616, the increase in the number of registered voters amounts to 28,466, there is an increase of 2376 in the number of houses built over those demolished, and there is an increase in the number of inhabited houses of 14,448. This latter figure was ascertained by a careful enumeration by specially instructed constables, whose returns were made upon specially prepared forms, and whose results as far as possible were afterwards checked. Local knowledge of the conditions of labour, of the action of the Insanitary Property Committee, together with other matters, must not be left out of sight as available means of checking the correctness of the estimate of the population. So far as the birth-rate is concerned, this, it is quite true, in certain districts in Liverpool is always high, but a remarkable increase in the birth-rates is exhibited since 1891 in the old parts of the city where the under-estimate of population is believed to be most marked. Excluding the suburbs recently incorporated the birth-rate in the old city (with a population of 497,505) is, upon the Registrar-General's estimate, 37·5, as against an average of 34·9 during ten years ending 1896. It is wholly improbable that a population with so high a birth-rate is diminishing as rapidly as the Registrar-General's estimate indicates.

If the City of Liverpool had not absorbed certain suburbs, the population of the city and those suburbs would have been calculated separately, and by the Registrar-General's method the resulting total would have been 11,051 greater than it is under the Registrar-General's method now adopted by which city and suburbs are calculated as one whole. In other words, extension to the suburbs of municipal government has, in the Registrar-General's opinion, lessened the population by 11,051. I have been in communication with the medical officers of health of the other great towns with a view to ascertain whether they consider the Registrar-General's published returns as to their own cities are dependable. The medical officers of health of 29 out of 31 of the other great towns have favoured me with their replies; 5 of them consider that the Registrar-General's estimate is fairly correct, 3 are very doubtful and express dissatisfaction with the method, whilst no less than 21 are of the opinion that the method is wholly incorrect and unreliable. No doubt the views of these gentlemen are merely expressions of opinion, but nevertheless their opinions are based upon local knowledge and are entitled to serious consideration. As regards the small towns the most conspicuous instance of error which I know is that of Bootle, the population of which, according to the Registrar-General's estimate, is almost 40 per cent. higher than what those with local knowledge believe it to be; the local authority have consequently discarded the Registrar-General's method entirely and adopted an estimate of their own.

It may be asked, What does it matter whether the returns are accurate or inaccurate? The importance of the matter is very considerable. There can be no doubt that if during the greater part of the decade ending 1891 the rate of mortality had been correctly published sanitary measures would have been more actively carried into effect. As it was, the decline in the rate of sickness and mortality shown by fictitious returns obscured the need for sanitary measures. Similarly, an under-estimate of population in certain districts masks the results of sanitary measures. Old rookeries are demolished, open spaces provided, artizans' dwellings on modern patterns are erected, and, so far as the Registrar-General's returns are to be taken as an index, the death-rate of the district is higher than it ever was before. Those who believe that the returns of a Government Department are carefully considered can only conclude that the pent-up rookeries were more wholesome than the new dwellings and that money and labour are spent in vain.

It does appear that there are good grounds for the view that the published returns of the Registrar-General should either be amended or accompanied by some explanatory note showing that after so long a period from the Census the figures are to be regarded only as approximately correct. I note with satisfaction your powerful advocacy of a quinquennial census, an advocacy based on the knowledge that the present returns are unreliable and need amendment.

I am, Sirs, yours faithfully,

E. W. HOPE.

Public Health Department, Liverpool, June 22nd, 1898.

ON THE NECESSITY OF A MEDICAL INFIRMARY FOR CHESTERFIELD.

To the Editors of THE LANCET.

SIRS,—The need of a medical infirmary has long been felt and for many years I have advocated its necessity, but hitherto without success. A majority of the governors and subscribers of the present surgical hospital are against admitting medical cases, as it is contrary to its original constitution, and they maintain that its invested money or reserve fund was left for surgical purposes only, as well as the money which was spent in the erection of the present buildings. There is, in my opinion, no probability that this determination will be altered in the present generation and meanwhile the sick poor continue to suffer. I have therefore for many years recommended the erection of a separate infirmary for medical cases. There is a population of 25,000 in the borough of Chesterfield and 120,000 in the district outside without any infirmary except the one at the union, which is almost always full and, indeed, crowded. The infirmaries at Sheffield and Derby are respectively twelve and twenty-four miles distant. I have, I think, made out a strong case for immediate action being taken. I think I am right in stating that there is no district in England with such a large and increasing population without such a charitable provision.

I am, Sirs, yours faithfully,

JOHN ROSE, M.D. Aberd.,

Honorary Consulting Surgeon, Chesterfield and North Derbyshire Hospital.

Chesterfield, June 22nd, 1898.

"THE COMING ELECTION TO THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND."

To the Editors of THE LANCET.

SIRS,—In view of the approaching election of members to the Council of the Royal College of Surgeons of England I have asked an expression of opinion from the various candidates, and especially from the two provincial ones, who naturally rely on the votes of the provincial Fellows. It seems certainly strange that, although circulars have been sent out on behalf of the latter gentlemen, no statement of policy or opinion on matters of interest to the Fellows has been made. Why this should be I cannot understand. Every candidate who is to be elected by the votes of a constituency, such as candidates for Parliament, &c., always makes some pronouncement as to their policy. Why not candidates for the Council? 1. As to the question whether Members should be admitted to some share in the management of their own Council Mr. May says: "I am opposed to any change in the present mode of election to the Council and the Presidentship." 2. With regard to the question of the Council taking action to check those Members and Fellows who act for medical associations who allow touting for members he says: "While I strongly disapprove of Fellows and Members holding appointments in which touting for sick members is allowed, and would support any reasonable and legal efforts to check this evil, I cannot promise beforehand to support any particular course of action which is unknown to me."

As to the point as to how the College representative on the General Medical Council is to be elected he says: "I am not

Digitized by Google

in favour of the election of the representative on the General Medical Council by direct vote of the whole body of Fellows and Members. I should be sorry to see this mode of election introduced and cannot promise support in that direction." I may say that Mr. Richardson Cross does not wish me to publish his letters to me about the matter, but I think I may say that he wishes to keep an open mind on these questions and whilst not definitely opposing does not promise to support any of these propositions. As I have been told on good authority that one more member on the reforming side would at any rate give a majority in favour of the last proposition I think it is a pity some candidate holding these views has not come forward on this occasion. I have not received any replies up to this date from the other candidates. Trusting you will publish this for the information of the Fellows of the College.

I am, Sirs, yours faithfully,

Portland-villas, Plymouth, June 28th, 1898. G. JACKSON.

THE SALINE TREATMENT OF DYSENTERY.

To the Editors of THE LANCET.

SIRS,—A recent correspondence in a contemporary shows that the treatment of dysentery by salines (especially sulphate of magnesia) is not as well known as it should be, several writers referring to it as something new. It was, I am informed, first suggested by Bartholow in his "Materia Medica," and for the past eight years it has been much used by civil surgeons in India, *vide* Leahy's paper,[1] Poynder,[2] and Walsh.[3] In the latter the rational treatment of dysentery is discussed. A reference to Surgeon-Major Leahy's valuable paper will show the advantages he claims for the saline over the ipecacuanha treatment. Salines have also been constantly used for years by French colonial surgeons. In my experience there are three kinds of dysentery met with clinically—viz., mild, acute, and chronic.[4] Anything will cure mild cases provided they get rest in bed and low diet. Acute cases in strong persons react splendidly to ipecacuanha in large doses (from 20 to 25 gr.). Other cases are best treated by sulphate of magnesia (saturated solution). The so-called chronic form of dysentery is very different from the above. There is nothing specific about it: it is a low gangrenous form of ulceration which occurs in cachectic cases and is frequently the terminal episode in such cases. It is found in cases of malarial or tuberculous cachexia, in cases which might be called sprue, in "famine diarrhœa," and among exhausted pilgrims going to and from the shrines of India. Such cases need infinite care and patience and a milk diet. The dysenteric stools alternate with diarrhœa or there are intervals of constipation. This form of alternating dysentery and diarrhœa with periods of quiescence much resemble clinically the so-called "amœbic dysentery," with the great difference that they are almost never connected with liver abscess. But nowadays we find few believers in amœbic dysentery (except in America). Even Kartulis, having shown the amœba coli in healthy stools, is less confident as to the pathogenic *rôle* of the amœba. Other more formidable microbes seem to be the active agents. To return to the question of treatment. Rest and sago diet will cure the mild cases in a few days, hence the *post hoc* success of numerous drugs, the latest of which is cinnamon powder. For acute dysentery in strong, sturdy Europeans or natives I give ipecacuanha in Scott-Doeker's method; in the weakly I prefer saturated solution of Epsom salts (two-drachm doses three or four times a day). For chronic dysentery ipecacuanha is best avoided, and castor-oil, soda, antiseptics, such as salol and bismuth may be tried; in some cases where there is an acute exacerbation use the Epsom salts, but general treatment and milk diet are above all necessary, and infinite patience. Perchloride of mercury with opium and tinctura nucis vomicæ are also useful in chronic cases and often prevent or postpone recurrences. Pages might be written on this subject, but unless we define the class or kind of dysentery met with there is no use in recommending any particular drug. The practical clinical distinction I have made above will prevent a too great belief in the powers of a drug which may only have been tried in mild cases which scarcely need drugs at all.

I am, Sirs, yours faithfully,

W. J. BUCHANAN, B.A., M.B. Dub.,
Surgeon-Captain, I.M.S.; Superintendent, Central Gaol, Midnapore.

May 18th 1898.

POISONING BY STRYCHNINE.

To the Editors of THE LANCET.

SIRS,—Dr. Robert Barnes asks in THE LANCET of June 18th, "What will the anti-vivisection bigot's say to this application of experimental science to the aid of justice"? Dr. Thomas Stevenson arrived at the conclusion that death was due to poison partly by physiological tests—i.e., he gave some of the poison to animals. To what animals? Falck says that serpents and fish experience no tetanic phenomena with strychnine and that the frog is really less susceptible to strychnia than various mammals and that it requires four times the dose needed by dogs, cats, rabbits, &c., to produce an equal effect on frogs. Stillé and Maisch[1] say that birds are comparatively insusceptible to the poison. Ten grains may fail to kill a sheep; cats resist it singularly and guinea-pigs and monkeys are said to be little affected by it. "The anti-vivisection bigots" would have some justification therefore for a little scepticism about the value of the physiological test in poisoning cases. Dr. Barnes says the experimental method teaches us how to treat convulsions. But surely we have all learned the lesson by clinical experience long ago. Why do all the books on poisoning by strychnine insist on the use of anæsthetics to keep the patient perfectly quiet so as to avoid the onset of convulsions if it be necessary to recur to animal experimentation for fresh lessons in treatment?

I am, Sirs, yours faithfully,

EDWARD BERDOE, M.R.C.S., &c.

Victoria-park-gate, E., June 21st, 1898.

*** Although the dose required by certain animals may be larger the result is ultimately the same. Resistance to poisons differs even in man to some extent.—ED. L.

"THE MEDICAL EXPERT AID COMMITTEE."

To the Editors of THE LANCET.

SIRS,—My attention has been drawn to an article appearing in your issue of June 18th, and at the request of the sub-committee of the above I desire to allude to certain matters to which reference therein is made. It is true that at present Dr. Woods is the only medical gentleman on the committee, one reason being that it is not and does not pretend to be anything but a number of ladies and gentlemen who (being well aware of the needs of the class for which it was formed, and of the fact that whenever the services of a medical man are really wanted, no matter whether he be a consultant or a general practitioner, those services are ungrudgingly and generously rendered to the patient, whether such patient can or cannot and regardless whether he will or will not pay the usual fee) desire to secure for such class of persons the services of the consultant, but upon terms that will secure to the consultant some recompense for his advice and at the same time remove the patient from the ranks of the hospital or non-paying patients. It is quite possible that the committee might be strengthened by the addition of medical men, and this matter I can assure you will receive the careful consideration of the committee.

You have alluded in your article to the number of hours a consultant spends in the hospital doing gratuitous work. This committee is well aware of such fact and is firmly convinced that a considerable portion of such time should be spent by such consultant in seeing some of the patients he now sees, but instead of seeing them in the hospital he should see them in his own consulting-room upon the terms that the patients so seen should pay to such consultant fees within their means, for if a patient can afford to pay a modified fee, surely he should pay such modified fee rather than nothing at all to the consultant. The consultant will give the patient the benefit of not a part, but the whole of his skill, learning, and

[1] National Dispensatory, p. 1363.

Digitized by Google

experience, and surely the patient should make as large a return as possible to the consultant. One of the aims of this committee is to ensure such a result. This committee is told that it is not always easy, neither is it desirable, that a general practitioner should, whenever he desires his patient to see a consultant, place himself under an obligation to such consultant, and if under the circumstances indicated an obligation is imposed, it is suggested it would be better for the same patient to see the same consultant by means of this committee and transfer the obligation from the general practitioner to this committee. It is perhaps using too wide an expression to say that a consultant would be putting himself into the hands of this committee were he to see patients recommended by the committee, for the plan adopted leaves the choice of the consultant entirely with the patient and his medical attendant, and every time a consultant sees a patient recommended by this committee he is specially asked so to do and can, of course, refuse or comply with such request; but in order that such patient may have as large a choice as possible and in order that it may not be suggested that the committee desires to further the interest of any special consultant or consultants, the committee has asked practically all the London consultants to see patients whom it has recommended. A large number of consultants to whom the circular letter was recently sent have sent replies, some consenting to see patients, others declining, and the refusals have (with two exceptions only) been most courteous and in numerous instances the objects of the committee have been approved in a most encouraging manner.

It is, of course, only natural that many (more particularly the junior) consultants, before complying with the request made by this committee will await the decision of their seniors and particularly of those in whom the governing power of the two great medical colleges is vested; and such being the case it is hoped that such decision may be based and given not upon any defect in the details of the scheme that may be readily cured, but upon the main objects of the scheme as disclosed in the circular, and that such decision may strengthen the hands of the committee and bring to the aid of that class of people to which I have already referred, the inestimable benefit of the services of the consultant in such a manner that the patient willing and able to pay something has the satisfaction of knowing that he has to the extent of his means recognised (although possibly not discharged) his liability to the medical or surgical expert of whose services he has availed himself.

I am, Sirs, your obedient servant,

S. GISSING SKELTON, Hon. Sec.

27, Lincoln's Inn-fields, W.C., June 27th, 1898.

A CORRECTION.

To the Editors of THE LANCET.

SIRS,—Permit me to draw your attention to a printer's error in the report of my speech delivered at the dinner of the Indian Medical Service. The mortality stated on line 17, page 1769, col. 2, in THE LANCET of June 25th, should be 0·4, and not 4, per cent.

I am, Sirs, yours faithfully,

June 24th, 1898. J. JAMESON.

THE SCHOOL BOARD FOR LONDON.

To the Editors of THE LANCET.

SIRS,—It is sincerely to be hoped that no medical gentlemen will offer themselves for the lectureships on "First Aid" and "Nursing" for the evening continuation schools of this Board. The object is apparently to cut the ground from under the ambulance department of the Order of St. John of Jerusalem and to get the work done at a lower cost. Truly the time of a medical man must be reckoned at a very low value to offer a fee of half-a-guinea for a lecture of two hours' duration. The medical officer of the School Board for London has, I should think, not been consulted in the matter, or if he has, he must have a very peculiar idea as to the amount of remuneration which professional services demand.

I am, Sirs, yours obediently,

June 27th, 1898. F.R.C.S.

"THE ALLEGED DEARTH OF QUALIFIED ASSISTANTS."

To the Editors of THE LANCET.

SIRS,—Permit me to say a word or two on the assistants' side of this question. I and others have advertised for assistancies and certainly our replies do not show that assistants are greatly in demand. One man offers me £60 per annum indoor; another would engage me at a fairly good salary if I were not a few pounds too heavy for his horse to carry; another wants a married man, as if on the usual salary offered a man in his senses dare marry; another still wants a single man; one offers an unfurnished house, which naturally suggests that he wants a man who has been an assistant before and will always continue to be an assistant; and another offers a small salary with a view to share in the practice after a certain probation (and if no agreement is made at first he is often found unsuitable at the end of his probation). Nothing much is said about the main question—whether the man is able to practise his profession intelligently. Again, I was tempted with the offer of £130 "out" with commission. On inquiry I found that the annual commission amounted to a little over £3. I have been told also by several gentlemen that they were compelled to engage qualified men on account of the action of the General Medical Council, otherwise they would not on any account employ qualified assistants. I think the main question is one of remuneration, as with the present salaries a man may spend his life as an assistant unless he has means or influence besides. In any case he usually spends the best part of his working life for the benefit of others. I enclose name and address, not for publication.

I am, Sirs, yours faithfully,

June 21st, 1898. M.D., M.CH.

To the Editors of THE LANCET.

SIRS,—I am one of those who appreciate the action of the General Medical Council in doing away with unqualified assistants. These latter, whether married or single, knew perfectly such would come to pass and should have been prepared for the inevitable either by getting qualified or seeking other employment. As has often been suggested, the General Medical Council should go further and put down quackery (herbalists and bone-setters) and prescribing chemists.

I agree with "M.A. Cantab., &c.," that tempting salaries offered by principals are very few indeed. I once got a situation having a tempting salary as I thought, but I found the work not very tempting—in fact, slavery night and day. My experience of principals is that they are as a general rule very selfish. When one applies for an assistancy he has to give references and testimonials as to character, &c., but is not to expect anything of that nature from the principal either as to himself or his wife, who sometimes "rules the roost," and regards the assistant as a "bottle-washer." The qualified assistant if he is expected to do his work in an efficient manner must be made comfortable in every sense of the term and neither have, as I have had, caterpillars cooked among his vegetables nor flies served among his beer, &c. I was in another situation where my sitting-room was the consulting-room, where many rough and dirty patients left their trace behind them, and the same butcher-meat appeared day after day till at last it appeared with the ribs exposed like the hulk of an old wreck one has seen thrown upon the beach. Yet, forsooth, this may be one of the principals who cannot get an assistant either through friends or agents. I likewise would like to see the position of qualified assistants improved—in fact, a unity among them by which they would be enabled to know about principals, &c., for they as a class have a great deal to endure.

I am, Sirs, yours faithfully,

June 29th, 1898. AN ASSISTANT.

SPANISH MILITARY MEDICAL SERVICES.

(FROM A SPECIAL CORRESPONDENT.)

THERE is nothing new in the idea of creating a laboratory for the manufacture by the State of the drugs, &c., needed by the army. A decree to that effect was issued during the reign of Philip V. It bears the date of 1737 and such a

Digitized by Google

laboratory was established at Melilla in the reign of Charles III. for the benefit of the troops in the Spanish African colonies. A ministerial order, dated April, 1787, sanctions the creation of similar laboratories at Malaga and at Madrid. The Malaga laboratory was the first to be completed and it remained in its original premises till the year 1888, when it was removed to a more commodious building. The Madrid laboratory was established at the end of last century in a private house in the Calle St. Bernardo and rendered great service during the War of Independence. Nevertheless this valuable institution was closed when the war was over. On April 5th, 1853, a new set of rules were published relating to the sanitary services of the army. These rules prescribed the creation of a laboratory and a central depôt of medicaments for the use of the army; but this official document did not amount to more than the expression of a pious wish. In 1873, however, what were called "executive regulations" were issued and reproduced the above project of a central laboratory. This was followed by a ministerial order directing that such an institution should be organised. It took, however, four years to carry out these instructions, for it was not till Nov. 26th, 1877, that the central laboratory and medical depôt of the military sanitary services was opened in the Calle de la Isla de Cuba, close to the Montaña Barracks. This was at first a very modest establishment, for the initial expenses only amounted to £1326. Medicaments were sent from this centre to the military hospitals in Spain and in the African colonies. Good work was done, and the services rendered were so obvious and the economies realised so great that all the authorities concerned gave every encouragement. Better appliances were purchased, a more numerous staff was employed, and early in 1885 much larger premises were obtained in the Calle de Amaniel. The laboratory during the first seventeen years of its existence cost 574,132 pesetas in building, &c., 150,589 pesetas in material, machines, and apparatus. The ground which it covers measures 2071 square metres and there is an annexe measuring 365 square metres.

The Central Laboratory now purchases the raw material and manufactures all the medicaments, drugs, chemicals, &c., required for the land and sea forces and their officers as also for the prisons of Spain and of all the Spanish colonies. The result has been a considerable reduction in the Budgets of the Ministers of War, of Marine, of the Colonies, of Justice, and of Public Worship. But apart from these public services arrangements were made by which generals, superior chiefs and officers of the land and sea forces can purchase from this State laboratory, either for themselves or their families, any medicaments they might need. This trade with the officers has yielded a profit during the first seventeen years of 423,543 pesetas, which has in great measure defrayed the expenses of installation. But this is nothing when compared with the immense saving in the purchase of medicaments for the army and navy. As already pointed out when dealing with the sanitary services of Cuba the economy effected in that colony since 1894 amounts to 5,766,722 pesetas. The cost of what was sent out from the central laboratory to Cuba amounts to 3,059,456. Had these medicaments, &c., been purchased in Cuba they would have cost 8,826,248 pesetas. A few figures will best illustrate the rapid growth of this institution. Thus in the year 1882 the amount of subnitrate of bismuth prepared weighed 110 kilogrammes. In the year 1896-97 the laboratory prepared 2000 kilogrammes of this medicament. In 1889-90 salicylate of bismuth to the extent of 25 kilogrammes was prepared; in 1896-97 the supply of this one article was equal to 1200 kilogrammes. At first but few powders were supplied to the hospitals. The laboratory did not possess the mechanical means of manufacturing them. The necessary machinery was obtained towards the end of 1893. In the following year 1639 kilogrammes of powders were produced. This production increased in the year 1898 to 12,309 kilogrammes of all sorts of powders.

To produce all these drugs there are two laboratories for the preparation of chemical products—one laboratory for special articles, such as trisulphides, alkaline solutions of tar, &c.; and a laboratory for what are called "specialities" such as pastilles, lozenges, granules, dragées, pills, &c. Then there is the machine gallery, which was installed in 1893. It is a large glass and iron hall containing a 12-horse power generator, retorts, evaporating apparatus, a 10-horse power horizontal gas engine, iron mechanical mortars, pulverisers, sifters, grinders, hydraulic presses, centrifugal motors for drying or precipitating crystals, extracting apparatus, &c. All these machines have been purchased from the best firms, and especially from French and German manufacturers. There is a department reserved exclusively for the packing and labelling of the medicaments and here some 6000 to 7000 different parcels are sent off every month. Then there is a laboratory for analyses, where all the products purchased are examined and tested so as to make sure that none but the purest drugs are employed. Water, pathological specimens, urine, &c., are also analysed in this laboratory, and altogether from 800 to 1000 analyses are made here during the course of twelve months. It has further been necessary to provide large warehouse accommodation to stock all the medicaments, &c. These amounted for the year 1896-97, if estimated in weight, to no less than 616,254 kilogrammes. Then finally there are the offices where the accounts and the ledgers, &c., are kept and made up.

In the annexe, situated in the Calle de Amaniel, the antiseptic dressing for wounds is prepared. This is quite a new installation and it was opened in August, 1897. The work had been done previously with considerable difficulty for want of proper apparatus. In June, 1895, the laboratory received orders to prepare the small packets of bandages which are supplied to each soldier, and which had previously been bought from private manufacturers. In the course of two years the laboratory produced 189,000 such packets, and these were so well arranged and of such good quality that they have been officially recognised as the best ever given to soldiers. Each packet must measure 11·5 centimetres in length, 7·5 centimetres in width, and 2·8 centimetres in thickness. It consists of a pocket or bag made of a waterproof tissue to which a printed label is affixed outside. This label replaces the card of identity which in several armies soldiers have to carry with them. The contents, to still further protect them and keep them clean, are wrapped up in a parchment-like piece of paper on which is printed a description of what the contents are and how they are to be employed. Finally, two pieces of cardboard impart stiffness and a regular fixed shape to the parcel. The contents consists of two compresses of absorbent cotton each weighing 2·5 grammes, two absorbent gauze compresses measuring 14 by 20 centimetres, two pads of absorbent cotton, a protecting piece of 20 by 25 centimetres in size, a gauze bandage 5 metres long and 6 centimetres wide, a triangular handkerchief, and two ordinary and two safety pins. One important consideration is the fact that this packet only cost 77 centimes, or about 7½*d*., to produce. But to make them quickly and cheaply it was necessary to purchase two machines so as to cut the cotton and gauze. Now that these machines are installed in separate and special premises the bandages can be prepared with great celerity and economy.

The manufacture by the State of the medicaments, &c., required for the army and navy, though admitted in principle some 150 years ago, has only recently been carried out on a large scale. The creation, however, of central depôts for all objects required by the military medical services is far more ancient. Such depôts existed at the times of the wars against the Moors and when Ferdinand and Isabella besieged Granada. To come to modern times, it was in 1853 that the establishment under one single manager of a central depôt was sanctioned. This was the commencement of the present organisation, and it was not in working order till six years later. Previous to that date the various army corps dealt directly with private purveyors and formed local depôts. What was thus purchased differed in nature and in quality, and there was no uniformity in the medical supplies of the army. During the African war of 1859 the first serious effort was made to enforce uniformity, and for this purpose a central depôt was established in the abandoned chapel of the old military hospital. Here were made the first stretchers. These were copies of the Austrian model and were sent to the seat of war. A Spanish model for stretchers was subsequently adopted. The chapel soon proved too small to store the various things required, and the central depôt was transferred to a private house in the Calle de Quiñones. Here there was more room to work at the manufacture of what is required for the ambulances or the transport of the wounded. A few ambulance waggons were constructed, as also boxes, &c., for portable pharmacies, surgical instruments, &c. In time it was again necessary to remove to larger premises, and on this occasion the old San Francisco barracks were selected. Finally in 1890 there was another removal to a still larger *locale* in the Calle de Palos de Moguer. The objects accumulated in this depôt are divided into three categories. First there is the

Digitized by Google

material required by an army corps for the care of the sick and wounded in war; secondly, the material suitable for an army corps on the peace establishment; and thirdly, the material necessary for the practical and theoretical instruction of all that relates to the ambulance and medical supplies required by an army. There is a technical committee for purchasing what is needed and for studying and testing all new inventions relating to these services. By the law of Aug. 30th, 1896, a special credit was sanctioned for military constructions, such as transportable field hospitals, ambulance waggons, and other means of transport for the sick and wounded and for the purchase of the most recent and improved surgical appliances. In course of time it is proposed to provide better portable stoves for baking bread and for cooking. Then it is also intended to construct branch establishments in various centres, receiving their supplies from the central depôt. For instance, at present the various local military hospitals have surgical instruments which have been purchased from time to time just as the opportunity or necessity arose. Some of these instruments may be of good make and quality, but many of them are undoubtedly very antiquated. In time all surgical instruments will be provided by the central depôt, where the most recent and best models alone will be manufactured or purchased. A military surgeon will thus wherever he goes find the same instruments; and this uniformity will be of great advantage in the surgical clinics. This uniformity will also bring about an economy of some 15 per cent. in the purchase of instruments. Instead of buying one instrument for one hospital a wholesale purchase of the same instrument for all the hospitals can be made and the above discount obtained on the quantity.

In connexion with the military medical services the Pathological and Anatomical Institute should likewise be mentioned. It was necessary to provide military surgeons with facilities for study and to encourage original researches. Means were to be supplied to test and to verify the importance and exactitude of all recent discoveries relating to the medical and surgical treatment of soldiers and sailors. The narrow compass of the old laboratories barely sufficed for this purpose. A Royal decree of Jan. 14th, 1885, approved the creation of an histological military laboratory. In bacteriological and chemical analysis this new institution soon rendered many practical services. In regard to hygiene and to many medico-legal questions the laboratory was also very useful. Consequently in 1888 a Royal order was issued enlarging the laboratory, to which a museum was attached, and it was henceforth called the Military Pathological and Anatomical Institute. Young army surgeons now follow a course of lectures and studies at this institute for six months and during that time they have opportunities of making original researches. But in 1889 when a portion of the old military hospital was destroyed by fire no less than 1450 anatomical specimens and wax models were consumed in the flames. Thus in a few moments the labour of years and a most valuable collection were irretrievably lost. Other dependencies of the institution were also much damaged, and a part of the library was only saved at great personal risk. The library has since not only been reconstituted but has been considerably enlarged and improved. It will take, however, many years before the new museum can compare with what existed before the fire. One of the most practical services rendered by this institution has been to study and improve all the services relating to vaccination and revaccination in the army. A special building was obtained for the production of calf lymph and its preservation in glycerine. The work that this has occasioned was particularly heavy in consequence of the mobilisation of large contingents of troops for service in the colonies. But the war, while entailing extra work, deprived the institute of many of its professors and students who were obliged to go to the front, and several of the members of the institute lost their lives in the colonial wars, notably Dr. D. Ramón Alba and Dr. D. Manuel Andrés. In spite of the loss of these professors, the researches, the teaching, the experiments and analyses were pursued with undiminished vigour, but not without entailing great fatigue and exertion on those who remained. Among other things no time was lost in utilising the discovery of the x rays for military surgery.

The studies pursued at the institute are divided into four sections. The first comprises all that relates to military hygiene and the preparation of vaccine-lymph; the second, descriptive anatomy, pathological topography, the manufacture of wax and other models for the museum; the third, pathological, chemical, and bacteriological history and chemical analysis; and the fourth, the spectroscope, radiograph, fluoroscope and micro-photography in their application to the medical sciences. After the fire at the old military hospital it was proposed that the institute should occupy one of the pavilions of the new Military Hospital now built at Carabanchel. But the services rendered were so great that it was finally decided to extend the scope of action of the institute and for this purpose it is proposed that in future it should be known under the more general term of the Institute of Military Hygiene. A scheme has been prepared by which 3780 square metres of the site of the old Military Hospital shall be set aside for the erection of a building planned expressly for the purpose and provided with cellars destined for the better preservation of lymph, serum, &c.

The Spanish Red Cross Society is constituted on the same basis as similar organisations existing in other countries and therefore in full agreement with the International Geneva Convention of Aug. 22nd, 1864. A Royal order issued by the Ministry of War called upon the Order of St. John of Jerusalem to organise the Red Cross Society for Spain and the rules and regulations then drawn up received Royal sanction in July, 1868. In 1874 the Red Cross Society was recognised by a special decree as the only authorised auxiliary to the regular medical services of the army. A Supreme Assembly, with its headquarters in Madrid, Calle de los Huertos No. 11 bajo, represents the society. It also possesses central commissions at Havana and at San Juan de Puerto Rico. Then there are provincial commissions in all the principal towns. The ladies' section has a similar organisation, and this institution was admitted as forming part of the International Red Cross Confederation by a circular of the Geneva Committee issued on June 6th, 1893. The uniform worn is recognised by Royal decree, and His Holiness the Pope, Leo XIII., granted on Dec. 9th, 1893, a plenary indulgence *in articulo mortis* to all its members. The Spanish Red Cross Society assists not only the sick and wounded in war, but also all who are the victims of some public calamity or accident. During the Carlist war in the North of Spain it rendered great services, and it was also the first to organise a maritime ambulance at the time of the cantonal insurrection at Carthagena. It further sent a fully equipped ambulance to Melilla during the recent war in Morocco. To Cuba and the Philippine Islands the Spanish Red Cross Society has likewise despatched an enormous amount of ambulance material and has established hospitals at Colon and Cardenas in Cuba. In the course of the first two years of the Cuban insurrection members of the Spanish Red Cross Society have nursed about 15,000 soldiers in the hospitals and some 25,000 on the battlefield and in temporary shelters or ambulances. The society also paid for several burials. It has spent about a million pesetas (£40,000) and has received gifts in kind worth about a third of that amount. Further, the society established at Madrid a sanatorium called the Hospital de Villa Hermosa, which was inaugurated in February, 1896. Here during the first two years 4461 soldiers were nursed and 16,237 medical prescriptions made up. His Excellency Lieutenant-General the Marquis of Polavieja is the President of the Spanish Red Cross Society.

From all these details it will be seen that some considerable progress has been achieved in Spain of late years in respect to the medical services connected with the army and the navy. What is more particularly remarkable is the fact that these reforms, far from involving a large outlay and thus tending to increase taxation, have, on the contrary, in some cases been a source of direct income and in other cases a means of effecting a great saving of expenditure.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Curative Serums for Plague. — The Propagation of the Disease.—Reports of Outbreaks.

THERE are two forms of curative serum for plague now being tried in India—one prepared by Professor Lustig which was introduced last year and gave some promise of success, the other by Professor Roux. The method of preparation

Digitized by Google

of the former has already been published but that of the latter is kept a secret until the results are considered to justify its publication. I shall look with great suspicion on any statistics which may be given from these experiments. In the first place, cases have been selected and in the second case the investigations have been chiefly carried out in a declining epidemic, when the virulence of the disease is less and the mortality lower than at any other time. When I say the cases have been selected I do not mean to infer that only the mild attacks have been chosen for inoculation, but that the cases have not been taken in the order of admission to hospital. As by a rough estimate it is probable that 30 per cent. of cases admitted to a plague hospital die within 24 hours and perhaps another 20 per cent. within 48 hours the importance of my contention is obvious. The later results with Professor Lustig's serum of greater strength are reported to be much more promising. These experiments are being carried out at the expense of the municipality of Bombay and it shows the active scientific enterprise and spirit of the corporation in that they have just voted more money for still further investigations. They are certainly doing a public service by offering these facilities for experiment during the present opportunity.

The evidence for the part played by the rat in the propagation of plague is gradually accumulating. At Karachi it has been a comparatively common observation for the occurrence of a case of plague to be preceded a few days by the finding of dead rats. This was particularly noticed in the first two or three cases of the present outbreak. The finding of dead or dying rats has now become the signal to clear out of any dwelling. Mice and cats have also been found to suffer from plague. Although so much attention is given to the disinfection of clothing the evidence that the contagion is ever conveyed by this means is very doubtful. The conveyance of infection by infected rats in grain-bags is much more probable as dead rats have been found among the piles of imported bags. As nearly every house in an Indian town is honeycombed by rat-runs and as the disease is very virulent in this species of animal, it is reasonable to assume that it is by their means that the disease is extensively if not chiefly spread. It is very certain that contagion from the sick to the healthy only accounts for a small proportion of cases. There is some evidence to show, however, that the so-called pneumonic form is more infectious than any other.

The number of cases reported in Calcutta is gradually increasing. The great exodus of people and perhaps the hot season may have combined to postpone its spread. The people are beginning to get over their fright and are said to be returning to Calcutta. They are also learning to see that the sanitary measures adopted when a case of plague is discovered are not so dreadful as they supposed. There are some signs also that inoculation will meet with more favour. Even in Bombay, however, less than 20,000 people have been inoculated, so that unless it be taken up on a very large scale it will have little or no effect on the progress of the epidemic. In Bombay the plague is almost extinguished and the average weekly mortality is nearly reached. In Karachi it is also very rapidly diminishing, the majority of the cases which are now occurring being found in the outlying camps. There is very little elsewhere.

June 9th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Infirmary Question.

THE question of the future of the Manchester Royal Infirmary is at present in a state of suspended, but only suspended, animation. Some short time ago it was intimated to the corporation, in answer to an inquiry as to the willingness of the infirmary authorities to sell the whole of the site in Piccadilly, that they were not willing to do so. At the meeting of the city council on June 8th, Sir John Harwood said he did not think anyone was satisfied with the present position of affairs. The alternatives seem to be either such an extension of the present site as to give space enough for rebuilding the infirmary on an extended scale or the sale of the whole of the site and the removal of the hospital to the suburbs. At present the latter idea does not find favour with the board, but it is possible that the enlargement of the power of dealing with the Owens College hospital estate recently received by the council of the college from the Charity Commissioners may before very long lead to a reconsideration of the question. By these powers the college can "alienate by conveyance or long lease" the hospital estate "to any person or persons, corporation or corporations, who may be willing and able to undertake to establish and maintain a hospital or hospitals upon the same land or part thereof, subject always to providing and securing to the medical school of the Owens College all requisite facilities for instruction," and also subject to safeguarding the provisions made in 1892 for the treatment of cancer. This arrangement would, in the event of purchase, allow of the new hospital being the actual property of the infirmary trustees, subject to conditions which would not be felt as a burden. The alternatives will no doubt be considered in all their bearings and a wise decision may be looked for some time or other. We must hope that it will be in the near future, for the infirmary is being worked at high pressure and much avoidable suffering is the result.

Grocers and Boric Acid.

There is a good deal of anxiety among grocers and milk-dealers as to the use of boric acid as a preservative for butter, bacon, milk, &c., and on June 9th a deputation representing some of the principal grocers of Manchester and Salford waited on Alderman Walton Smith and other members of the sanitary committee of the Manchester Corporation and requested them not to prosecute retail traders just yet. The committee were asked "not to take any active steps in the way of prosecuting retailers of bacon and butter preserved with boracic acid but to stay their hand until a standard has been fixed by the medical authorities connected with the Board of Trade." If the time for fixing this standard is calculated at the customary rate of departmental progression the users of boric acid may hope for a long innings. The deputation pointed out that there was "a great conflict of medical opinion" as to the wholesomeness or otherwise of boric acid as a preservative and said that it had been in use for twenty years without any injurious effects so far as could be ascertained. The committee promised to give the matter their serious consideration but could not make any definite statement as to the course which would be adopted. It is said, by the way, that thoroughly well-made butter—a comparatively rare article perhaps—will keep a fortnight even in hot weather without any artificial admixture, so that the acid is no doubt often used to cover the carelessness which causes an inferior make. At the Chester police-court the other day a farmer was summoned for selling milk mixed with boric acid. The city analyst had certified that "the sample contained boracic acid to the extent of six grains per pint, which quantity would be injurious to the health of young children." It was stated for the defence that it was used in ignorance and that "the defendant put the powder in the milk to preserve it on the assurance of a chemist's commercial traveller that it was not injurious and was allowed by Government." Some check might with advantage be placed on the persuasive eloquence of commercial travellers. It is quite time that if anything is really known as to the effects of the continued use of boric acid in small doses it should be authoritatively set forth and the law as to its employment be clearly stated.

Lamp Throwing at Hyde.

Some folks may be glad to know that at the neighbouring town of Hyde the amusement of throwing lighted paraffin lamps at your wife—probably if at anyone else it would cost more—may be indulged in at the moderate charge of half-a-crown. It is much less expensive than golf. John William Hague has proved this, for on reaching home late at night on June 11th, having previously taken care to get drunk, he began to abuse his wife and as she ran to the door to escape into the street he picked up the lighted paraffin lamp from the table and threw it at her. Fortunately his aim was faulty, but the lamp struck the door and was smashed to pieces, part of it flying into the street. Happily the flame went out in its flight and no further mischief followed. When taken before the magistrates he was fined half-a-crown and costs, and the chairman in reprimanding him made the incontestable remark that lamp-throwing was dangerous, adding moreover that "it would pay him best not to indulge in it any more." One of the other magistrates told the

Digitized by Google

prisoner he might have been "before the bench" for manslaughter. He got off cheaply, for these hard words broke none of his bones, but no doubt the cost of the game may rise as it will vary according to the magistrates' views of sport. It does not seem that any addition to the fine was made because the man was drunk, so that it may be asked if it is considered the normal condition at Hyde for the "lords of creation" to be drunk on a Saturday night. No doubt the British working man deserves much of the good that is said of him, but there are exceptions. A drunken Englishman is always a nuisance and too often a dangerous brute to whom such punishment as that inflicted at Hyde is a joke and an incentive to continue the game.

June 21st.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Glasgow University.

IT is officially intimated that Her Majesty the Queen has been graciously pleased to signify her approval of the appointment of the Rev. Dr. Story as Principal of the University in succession to Principal Caird, resigned. Dr. Story has been Professor of Ecclesiastical History in the University since 1886; he is one of the Queen's chaplain's and principal clerk to the General Assembly of the Church of Scotland. The University Court have sent a letter to Principal Caird expressing their regret at his resignation and their high appreciation of the ability and devotion he has for so many years displayed in the service of the University.—It has been decided that the classes of Materia Medica and Therapeutics at Queen Margaret College shall next session be conducted by a specially appointed lecturer and applications for the position are invited by the Court.—The final examinations for degrees in medicine come to a conclusion this week and the list of successful candidates will be issued in a day or two. The session at the Royal Hospital for Sick Children was closed on June 27th by an address from Professor McCall Anderson. Prizes for excellence in clinical work were awarded to Mr. D. S. Harvey and Mr. A. S. Wells.

Glasgow University Club, London.

The members of this club dined together at the Café Royal on the evening of June 22nd. The chair was taken by Professor William Macewen, F.R.S., who met with a most hearty reception from the large assemblage met especially to do him honour. The toast of the chairman was proposed by Dr. Heron in a very neat and witty speech and was enthusiastically received. Professor Macewen, in reply, gave a number of very interesting particulars concerning the origin of the antiseptic system in Lister's wards in the Glasgow Royal Infirmary and expressed his personal indebtedness to Lister's work and stimulus. The dinner was in every sense a great success.

Hospital Saturday in Aberdeen.

Last Saturday was "Hospital Saturday" in Aberdeen. As usual the friendly societies took charge of the movement. The usual procession to Duthie Park and sports took place, and the committee expect to have a surplus of £1000.

The Sanitary Inspectors' Association.

The annual Congress of the Sanitary Inspectors' Association of Scotland was opened in Perth on June 24th under the presidency of Mr. Kenneth Cameron of Aberdeen. Mr. Cameron's inaugural address was an excellent one. An interesting paper on Sanitation in Perth, 1868 and 1898, was read by Ex-Baillie Alexander, Convener of the Public Health Committee of Perth.

June 28th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Conjoint Examinations in Ireland.

THE Secretary of the Committee of Management of the Conjoint Examinations of the Royal College of Physicians of Ireland and the Royal College of Surgeons in Ireland has recently made a public announcement addressed to possible candidates for the preliminary examinations to be held during the year 1899. Candidates are informed that considerable changes have been made in the course and are referred to the secretary, Mr. Greenwood Pim, M.A., for particulars.

The Royal Irish Academy.

At a meeting of the Royal Irish Academy held on June 13th the President, the Earl of Rosse, K.P., occupying the chair, Mr. William Frazer, F.R.C.S. Irel., was elected a Member of Council and Librarian in the room of the late Sir John Gilbert.

The Royal Hospital for Incurables, Dublin.

A meeting of the Board of the Royal Hospital for Incurables was held on June 21st, Sir William Fry occupying the chair. A strong resolution expressing the loss which the institution has sustained in the recent death of Mr. Edward Fottrell, for so many years an acting governor of the hospital, was passed unanimously.

The Belfast Union Workhouse.

The Special Committee of the Belfast Board of Guardians, which had been appointed to take into consideration the report furnished by the Local Government Board Inspectors,[1] have replied that they were of opinion that the deficit at the end of the present financial period would not exceed £10,000. Having conferred with Dr. Bigger they were of opinion that the hospital staff should consist of 9 trained and 11 probationer nurses. With reference to Mr. Agnew's remarks about the quality of the beef supplied to the inmates they believed that it was in accord with the terms of the contract which required that it should be supplied from "fair finished beasts." At a meeting of the guardians held on June 21st the report of Mr. Agnew was read in reference to the inquiry into the treatment of a child. The report stated that a serious and lamentable neglect of duty had occurred on the part of the nurse and medical man in charge in facilitating and sanctioning the discharge of the child from the infirmary until they had satisfied themselves by an interview with the mother that she had thoroughly understood what the condition of her child was and that she having such knowledge insisted upon taking her child out of the infirmary. They thought both the nurse and medical man should be censured and this course was acted upon by the board of guardians, who called before them the nurse and medical man and reprimanded both.

Monaghan and Cavan Asylum.

Some time since the governors of this asylum wrote to the Monaghan guardians for the temporary use of the vacant wings of the workhouse for the accommodation of harmless lunatics and the guardians agreed to do so provided the Local Government Board concurred. The Local Government Board, however, would not sanction the arrangement. The governors, at their meeting on June 22nd, having considered the necessity for additional accommodation owing to the extremely overcrowded condition of the asylum, resolved that steps should be at once taken to put up an auxiliary building sufficient to accommodate 120 patients, together with such additions as may be absolutely required for sanitary and cooking purposes, at a cost not exceeding £5000.

Newcastle as a Health Resort.

For strangers visiting the north of Ireland there is no more beautiful health resort than Newcastle. Situated at the foot of the Mourne Mountains in co. Down it commands the most lovely charms of mountain, sea, and wood, and from a tourist's point of view its value and comfort have been immensely enhanced by the erection of a new hotel which was opened by the Countess of Annesley on June 21st. From a medical point of view Newcastle is mild, comparatively dry, and it affords great varieties of sea and mountain air; and there are beautiful coach drives in the district as well as in the neighbouring noblemen's parks, while close to the hotel, exposed to the bracing sea air, there are as fine golf links as are to be found anywhere. Newcastle is about one hour's run from Belfast by train, while on the other side it can be approached by drive from Warrenpoint along a most delightful and bracing stretch of country.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Serum Therapeusis in Mushroom Poisoning.

THE possibilities of serum therapeutics are by no means exhausted, for every day sees some new application. A case of poisoning by mushrooms has afforded M. Claisse the opportunity of trying a treatment the details of which he laid before the Society of Biology at the meeting of June 18th. It is well known that two widely different substances take part in this kind of poisoning. The one, muscarine, brings about violent gastro-intestinal disturbances; the other, phalline, is more subtle and more alarming and both the guinea-pig and the rabbit are very sensitive to its action. Five milligrammes of powdered amanite per hectogramme will kill a guinea-pig if injected under the skin. M. Claisse, however, demonstrated that immunity is very quickly established and that after 50 days a rabbit will easily support a dose of triple the ordinary fatal strength.

Retention of the Placenta in Abortion.

At the meeting of the Obstetrical Society held on June 9th M. Loviot reported the case of a patient in whom after having aborted the placenta was retained for 101 hours. The general condition of the patient being satisfactory and the after-birth being everywhere adherent M. Loviot determined to adopt an expectant treatment. He give intra-uterine injections of permanganate of potassium and administered one grain of sulphate of quinine in the 24 hours, a drug well known to be an excellent oxytoxic and one which has an advantage over ergot in that it does not cause tonic contraction of the uterus. Contractions were soon set up and the placenta was expelled. M. Loviot considers that in cases of this kind the use of corrosive sublimate must be guarded against, for it is very easily absorbed, the placenta acting as a sponge.

The Dental School of Paris.

The council of the Dental School and Dispensary of Paris, the committee of the Paris Odontological Society, and the council of the General Association inaugurated on the evening of June 25th the new buildings of the Dental School of Paris. After the establishment had been inspected a banquet followed, Dr. Lecandey, the honorary president of the association, being in the chair. The following morning there was a meeting to consider the forthcoming Congress of 1900, also a clinical meeting of the Odontological Society, and the prizes and diplomas for the scholastic year 1896–1897 were distributed to the pupils of the school.

The Bacteriological Laboratory of the Prefecture of the Seine.

The monthly report of this laboratory for May shows that 267 specimens were submitted for diagnosis. There is a remarkable diminution in the figures for material from doubtful cases of diphtheria sent in, but the percentage of undoubted diphtheria is almost the same as that of the preceding month—namely, 12 per cent. The diphtheria mortality continues to steadily diminish. For the month of May, 1897, there were 21 fatal cases, while during the corresponding month of 1898 there were but 15. Of 106 examinations made during May for other diseases 93 dealt with material suspected to be tuberculous and in 38 of these the bacillus of Koch was found. Although suspected cases of diphtheria are becoming fewer suspected cases of tuberculosis continue to be sent up in increasing numbers.

Glycosuria in Wet Nurses following the Administration of Somatose.

Glycosuria is not uncommon in wet nurses and so M. Renon in attributing this condition to somatose, as he did at the Hospitals Medical Society on June 17th, has probably been misled by a mere coincidence. The case in question was that of a wet nurse aged forty years. It is well known that Dreux and Joachim have shown that the ingestion of somatose is an admirable way of increasing the flow of milk and Renon has administered it to this end with great success. In the case reported by him the urine at the end of the three weeks contained sugar to the amount of 3 grammes to the litre. Upon the somatose being left off the urine became normal. There is one fact which goes to show that the glycosuria was a direct consequence of the somatose—i.e., that diabetics pass more sugar when they eat meat; such, at least, was the result of some observations by Naunyn and Lepine. Might the glycosuria in this case, however, not be due to the over secretion of milk—that is, as Lecorche has shown, be due to the absorption of some of the sugar secreted by the breasts? The somatose in that case would have gone beyond its duty by increasing the milk too much. M. Legendre declares that for his part he has never seen a parallel case.

Obituary.

On the morning of June 21st Dr. Genouville, who had been visiting a patient, fell from the fourth floor of a house into the courtyard and was instantly killed. He was in his sixty-first year and was treasurer of the Association of Medical Men of the Seine. An inquiry will be held.—Dr. Auguste Felix Voisin has recently succumbed to anthrax. He was the son of a physician and was born at Paris in 1829. He graduated as Doctor of Medicine in 1858 after having served as *interne* at the hospitals. He was physician at Bicêtre where he studied mental diseases. He was a member of the Anatomical Society, of the Medical Observation Society, of the Medical Society of the Seine and of the Council of Hygiene and Public Health. In 1869 he became connected with the Salpêtrière. Among the many works upon mental diseases which he published may be mentioned, "The Mental States in Alcoholism," "On the Curative Treatment of Mania," "A Treatise on General Paralysis in the Insane," and he was many times rewarded by the Academy of Medicine for his scientific work. Dr. Voisin was in addition *officier* of the Legion of Honour.

June 28th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Professor Koch on Malaria.

AT the last meeting of the Berlin Colonial Society, Professor Koch, who has recently returned to Germany after a long absence in India and South Africa, read a paper on Tropical Malaria. There was a large attendance of members and visitors belonging to the medical profession, who received Professor Koch with loud applause on his entrance, and although he spoke on medical subjects before a mixed audience his hearers listened with the greatest attention for the two hours during which the proceedings were continued. He said that malaria is the specific disease of the tropics; it is the most terrible enemy there is to contend against in these regions, and the full advantages of the colonies will not be realised until it is overcome. The first step in meeting it is to know how it arises. For this purpose Dr. Koch has investigated a tropical disease of cattle which is somewhat like malaria. This disease is the so-called Texas fever, the cause of which has been stated by Smith to be a parasite—parosoma bigeminum. The parasite is present in the blood of the animals and its germs are spread by insects called "ticks." Cattle coming from the north only catch the disease when ticks have access to them. Professor Koch, to verify the statement of Smith, made the following experiment. He collected ticks from healthy as well as from sick cattle and took them to a distant place where Texas fever had never yet occurred. Healthy cattle were then inoculated with the eggs of ticks of both categories, the results being that the eggs obtained from sick animals gave Texas fever to the inoculated cattle, whereas the eggs from healthy animals produced no effect. Cattle reared in places where the fever was endemic did not always show this reaction, apparently because they had suffered from it when young and had therefore become immune against it. Some of them became infected, but in a slight degree only. It is thus possible to obtain an artificial immunity against Texas fever. Malaria, like Texas fever, is caused by parasites in the blood. Laveran and some Italian pathologists detected in the red corpuscles a specific parasite which is very motile and grows somewhat quickly. The climax of its development coincides with the maximum temperature during the fit and it afterwards breaks up into spores which again invade other corpuscles. There are two clinical forms of malaria; one, occurring in Europe, is characterised by a regular course of fever, as quotidian or tertian malaria, the second or malignant form, which only develops in hot climates, shows a very irregular temperature. The relation of the parasites to the different kinds of fever has not yet

Digitized by Google

been ascertained. There was no strict indication in the treatment of tropical malaria, as quinine was given at random without considering at what time it might be most efficacious. As a rule it was taken in divided doses throughout the whole day. By microscopical investigation Professor Koch has now discovered that quinine will most surely overcome the parasite at the period preceding the above-described sporulation. The time when quinine must be taken is thus to be determined in the individual case by microscopical examination of the blood, and Professor Koch called special attention to the fact that quinine administered at the right time is able to cure the disease. When the fever has ceased one gramme of quinine must be administered every five days for two months. Blackwater fever, in his opinion, is not due to malaria, as parasites have never been found present in these cases, but is the result of a toxic effect produced by quinine. With respect to the mode of infection Professor Koch said that various conjectures have been made, but nothing is definitely known, and it has not been ascertained how the parasite enters into the blood of the patient. There is no direct infection from one person to another, the malady not being contagious, and infection by air or water is not likely. Diseases, however, are known in which infection is conveyed by insects, as in Texas fever, and it is remarkable that there is no malaria where there are no mosquitoes. This is, for instance, the case in some islands near the African coast and in the Usambara country. The mosquitoes probably deposit their eggs on the human body, the parasites issue from these eggs, and when their number has increased the disease develops. The time of incubation is about ten or twelve days. As to immunity Professor Koch is of opinion that persons who have once caught malaria and have recovered spontaneously without quinine possess a certain degree of immunity. The natives of the coast, who never catch malaria, owe their immunity to the circumstance that their ancestors have passed through the disease. If, therefore, a natural immunity is possible it may be hoped that means of producing artificial immunity may be discovered some day. The measures which have hitherto been used against malaria, such as draining of marshes, planting of eucalyptus trees, and establishment of sanatoria in mountain districts, have failed. What is wanted is to teach the medical men in the colonies how quinine should be given and to construct the dwellings of the Europeans so that the mosquitoes may be kept off. In conclusion Professor Koch said: "When we are able to destroy malaria in our colonies we shall have peacefully conquered one of the most beautiful and fertile countries of the world."

June 28th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Medical School.

A PRELIMINARY list of teachers, mostly already connected with Kasr el Aini Hospital or school has now been sent to the Council of Ministers for their formal approval. After October, both the hospital and school will be controlled by one director aided by two committees. The school, as now, will consist of four sections, male medical, female medical, pharmaceutical, and veterinary. The summer examinations have just ended, so that it may be seen how many students the new staff will find after the holidays. The fourth and final year will consist only of 7 students on the male medical side, the third year will only have 5, but the second year will muster 15, and for the entrance year there are already 12 applications. All candidates for admission must have the secondary certificate. This year there is great tribulation on the French side of the secondary schools, because they have been well beaten by the English side at the final examinations. The test must have been severe, for only 98 passed out of a total of 344. French is still the dominant language in the Government schools, to our shame be it said! In the primary schools, where the parents of the boys must first choose the prevailing language, 51 per cent. learn English and 49 per cent. French. But in the secondary schools the percentage is 63 French and 37 English. The animal stables attached to the medical school have now been finished in the most workmanlike and satisfactory way. They are already stocked with a limited supply of horses, donkeys, goats, dogs, cats, guinea-pigs, rats, foxes, and monkeys.

Infectious Hospital.

The pavilions and huts for infectious diseases in the desert continue to be most useful and probably they save Cairo from the smouldering of many small epidemics. At the present moment there are under treatment there 61 cases of relapsing fever, 2 of typhus fever, 1 of small-pox, and 2 of erysipelas. During the spring months there were 300 admissions of relapsing fever, mostly from the prisons, and 21 of these died. The greatest number of relapsing patients present on any one day was 130. As many as 7 of the attendants have caught the disease this year, but all recovered.

Vaccine Institute.

This establishment is gradually extending its usefulness and will shortly be able to supply calf lymph to the whole of Egypt. The receipts last year included £200 made by selling lymph to the Egyptian Army and to the Alexandria Municipality. Cultures of lymph come every week by post from Europe, but for the last two summers it has been possible to keep up the local supply. The secret of this success is that many more calves are now being used than in former years. It is still found that buffalo calves are much more susceptible and more certain in their results than cow calves. The institute last year provided lymph for about 50,000 vaccinations and 330,000 in the whole country were returned as having been successfully performed. However, no less than 2057 cases of small-pox were treated in the Government hospitals in 1897.

Statistical Returns.

A comparison of the two years 1881 and 1897 has lately been made by Sir E. Palmer to show to what extent Egypt has profited under British rule. A few figures from this return may be briefly quoted. The population of Egypt has increased by 43 per cent. The tobacco-tax now brings in over £1,000,000 instead of £97,168. This is partly due to the flourishing export trade in Egyptian cigarettes. Tobacco is the only tax which has been raised; many others have been reduced or abolised altogether. Two hundred and twelve miles of new railways have been opened and there is a huge development of railway and postal and telegraph traffic. The expenditure on public education has been raised by over 37 per cent. and the schools from 29 to 51. The number of forced men for corvée work is reduced from 281,000 to 11,000. The amount of debt per head of the population was £14 per cent. in 1881 and is to-day £10. Lastly, the 4 per cent. Unified Debt, which is the pulse-rate of Egyptian finance, was at £71 in 1881 and at £106 in 1897.

Cairo Tourist Season.

The last winter season was crowded enough to satisfy all the hotel keepers. About 7500 tourists, mostly English, Americans, and Germans, landed in Egypt between November and April. This number almost reaches the maximum year. Medically speaking the season was a very healthy one, slightly marred by dengue in the autumn, while in the spring, as in many past years, influenza was imported by patients from Europe. The weather was decidedly cold throughout, being the exact reverse of the winter of 1896–97.

Luxor Hospital.

This small hospital of 26 beds continues to do very useful work. It has been supported since 1891 chiefly by the subscriptions of tourists. The late Mr. Longmore took a great interest in its foundation and maintenance, and the winter work is now to be continued by Surgeon-Major Elcum. The hospital remains open during the summer months under the charge of a native medical officer, to whom patients travel from villages 200 miles above Luxor and from places almost 200 miles to the north. Every day there are about 20 new out-patients and the number of surgical and eye operations in the month averages 20.

Cairo, June 19th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Graduation in the Dental Department of the University of Pennsylvania.

IN order that the entrance requirements shall be in harmony with those of the other departments the University

Digitized by Google

will hereafter require the following preliminary education in the dental department: for the session of 1898 to 1899 a certificate of high-school entrance; for the session of 1899 to 1900, a certificate of two years of high-school attendance; for the session of 1900 to 1901, a diploma of an approved high school having a three years' course or a certificate showing three years' attendance at a high school having a four years' course or certificates from other schools showing equivalent education. In lieu of such diplomas or certificates the candidate will be required to pass a matriculation examination which shall be the equivalent of that necessary to obtain the certificates above mentioned.

Results of Treatment of Tuberculosis at Loomis Sanatorium.

This institution was established by the friends of the late Dr. Loomis for the treatment of persons suffering from tuberculosis. It is located about 100 miles from New York on the Catskill Mountains. From the report of the physician it appears that during the first year 8 per cent. of the patients discharged had lost their tubercle bacilli; during the last six months covered by the present report 18 per cent. of those discharged had lost their bacilli. During the first year 73 per cent. of those discharged had gained in weight, while during the last six months 81 per cent. of those discharged had gained in weight. During the first year 13 per cent. of the patients discharged were apparently cured, while during the last six months 23 per cent. of those discharged were apparently cured. Last year 10 per cent. were discharged with their disease arrested and during the last six months 9 per cent. It is interesting to note that of those patients discharged after a residence of three months or less at the sanatorium 17 per cent. were apparently cured, while among those who were discharged after remaining longer than three months 26 per cent. were apparently cured. This is a good object-lesson for those physicians who send their patients with the advice that they should remain six weeks or two months. The basis of treatment in all cases has been climatic and hygienic. The climate of Liberty and the site of the sanatorium are well adapted to the treatment of tuberculosis throughout the whole year, but there is even more marked improvement during the winter months than in the summer. The elevation, 2300 ft., is within those limits generally conceded to be most advantageous for lung troubles; this altitude with the peculiarly dry atmosphere and abundance of sunlight furnishes all the conditions necessary in the climatic and hygienic treatment of incipient cases of tuberculosis. Malarial fevers are unknown at Liberty except when imported. While strong winds are generally supposed to be detrimental to the class of patients under consideration they bear well cold and north-west winds. The experiences encountered and the results obtained during the two cold seasons at this sanatorium seem to tend to revolutionise the popularly accepted ideas of the injurious effect of winds and stormy weather upon incipient cases of tuberculosis. A good deal has been said and written against allowing phthisical subjects to walk or to exert themselves to any great extent, especially if their temperatures range above the normal point. It is a rule at this sanatorium to allow all patients whose evening temperatures do not reach above 100° F. to walk moderately and if their temperatures are not above 99° no restrictions at all are placed upon them in this respect, but they are encouraged to gradually accustom themselves to pedestrian tours extending from two to ten miles daily. In the way of specific treatment of individual cases creasote and its derivatives have been used. Of the different forms guaiacol valerianate has been more extensively used than during last year, as it is the form of this drug least irritating to the stomach which has been met with. Ichthyol in keratin-coated pills has been used with considerable success; this remedy seems specially beneficial in cases showing intestinal complications. In regard to the serum treatment 7 out of the 29 cases thus treated, or 24 per cent. of the cases, lost their tubercle bacilli and in 48 per cent. the bacilli decreased. In an examination of 15 cases treated by serum not one had redeveloped the disease; on the contrary, all have been enabled to remain in their homes and at their work.

Medical Aid during Action.

Dr. Spear, an assistant surgeon of the United States Navy on board the flagship *New York*, writes as follows on the duty of the surgeon during action: "When 'general quarters' is sounded aboard the U.S.S. *New York* the sick-bay is immediately converted into an operating-room; an operating-table is placed in the centre, the ordinary instruments for amputating limbs are arranged in trays and immediately disinfected by steam, aseptic dressings are laid out, and antiseptics prepared for immediate use. It becomes the duty of medical officers to take measures to stop all bleeding from wounds. To do this the crew of each gun receives instructions in first aid to the wounded by the medical officers. Each gun has its own outfit of rubber tubing and packages of aseptic dressings. The men are instructed how to apply the rubber tubings to the limbs in order to arrest hæmorrhage, how to apply aseptic dressings, being especially cautioned against touching wounds, and, finally, how to support limbs when broken and how to carry the wounded and where to place them. The medical men take their stations in the most protected parts of the ships—viz., behind the turrets—and here establish dressing stations and attend to all the wounded in the immediate vicinity. The surgeons have received orders to expose themselves as little as possible during action as their real work begins when the fight is over. Each surgeon carries a haversack in which are pieces of rubber tubing for controlling hæmorrhage from the extremities, hæmostatics, a pocket case, hypodermic syringe, and solutions of strychnine and morphine ready for hypodermic use, and some first aid packages. Stationed with each doctor is a nurse, who carries in a knapsack surgical dressings, antiseptic solutions, whisky, and so forth. When the action is over the surgeons will take a hasty survey of the wounded and give such attention as is absolutely necessary to each. When the wounded have been attended to those cases needing immediate operation will be looked after, three operating tables being established if necessary."

June 18th.

Obituary.

HENRY CASE, M.R.C.S. ENG., L.S.A.

HENRY CASE was born in London on June 28th, 1843, and spent his boyhood in West Herts. On leaving school he became the pupil of the late Dr. Ambler of Hemel Hempstead, after which he proceeded to Middlesex Hospital, from which medical school he qualified; becoming M.R.C.S, Eng. in 1867 and L.S.A. in 1868. He was appointed subsequently house surgeon to the hospital and as such he displayed an amount of zeal and efficiency which gained him golden opinions from all concerned. On leaving Middlesex Hospital he was appointed house surgeon to the West Herts Infirmary and this office he held for over three years. So thoroughly did he do his work that on resigning that office in 1873 to become assistant medical officer in the Metropolitan District Asylum at Leavesden, the Infirmary Board formally put on record their high appreciation of his services and expressed their regret at not having the power to mark their appreciation in such a tangible manner as they would have wished. After nearly three years' work as assistant medical officer at Leavesden he became medical superintendent of the Asylum at Hampstead under the same board, and shortly afterwards this asylum was converted into a small-pox hospital, which he managed with singular success. In the autumn of 1876 he succeeded Dr. Claye Shaw—the present medical superintendent of the London County Asylum, Banstead—as medical superintendent of Leavesden Asylum, which office he held until ill-health compelled him to resign in January last. For some six years after 1876 he was Lecturer on Psychological Medicine at the Middlesex Hospital, but finally he had to resign this appointment on account of the onerous nature of his daily work at Leavesden. He performed his duties at Leavesden with ability, tact, and rare vigilance—a vigilance so unceasing that his duty became alike his work and his hobby. He kept pace with current medical literature, displayed great diagnostic power and ripe judgment, and wielded a most humanising influence over his unfortunate patients, and his high qualities as gentleman and physician attracted to himself the ready obedience, respect, and love of his staff. Always of modest and retiring disposition it was only by those who came in daily contact with him that his conscientious labours and sterling worth were fully appreciated

Digitized by Google

but within the large institution which he administered so faithfully and so well and among his friends—who include his colleagues and all who knew him—the memory of his noble character and much loved personality will long remain. He leaves a widow to mourn her loss and to her goes out the respectful sympathy of all who loved her husband.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having passed the necessary examinations have been admitted Licentiates in Dental Surgery:—

William Monro Anderson, Lewis Fryer Barton, William Henry Bean, Surg.-Capt., M.R.C.S. Eng., L.S.A. Lond.; Frank Russell Bishop, George Parminter Cardell, Alfred Eastland Carden, Harold Cardwell and Frank Coleman, Charing Cross and the Dental Hospital of London, Sidney d'Alton Corbett, St. George's and the Dental Hospital of London; Frederic Ledger Etheridge, St. Bartholomew's and the National Dental Hospital; Sydney William Garne and Zephaniah Job Gibson, Charing Cross and the Dental Hospital of London; William James Grewcock, Mason University College, Queen's, General, and the Dental Hospital, Birmingham; Hubert Malcolm Griffiths, Middlesex and the National Dental Hospital; John Harper, M.R.C.S. Eng., L.R.C.P. Lond., St. Thomas's and Guy's Hospital Dental Department and School; Herman Charles Hessenauer and Frank Holding, Charing-cross and the Dental Hospital of London; Reginald Crompton Holt, University College, Royal Infirmary and Dental Hospital, Liverpool; William Warwick James, Middlesex and the Dental Hospital of London; George Frederick William Jennings, Charing-cross and the Dental Hospital of London; William Henry Jones, Owens College, Royal Infirmary, and Victoria Dental Hospital, Manchester; Harry Percy Joscelyn, Mason University College, Queen's, General, and the Dental Hospital, Birmingham; William Henry Loosely, Guy's Hospital, Dental Department and School; Arthur Robert Marks, St. George's and the Dental Hospital of London; Charles Ernest Mountford, Mason University College, Queen's, General, and the Dental Hospital, Birmingham; Edward Giles Narramore, University College, Royal Infirmary and Dental Hospital, Liverpool; William Nicholson, Owens College, Royal Infirmary, and Victoria Dental Hospital, Manchester; Charles Deane Outred, Guy's Hospital, Dental Department, and School; Alfred Mitchell Partridge, University College, Royal Infirmary, and Dental Hospital, Liverpool; Howard James Paterson, Mason College, Queen's, General, and the Dental Hospital, Birmingham; Oliver Grace Penfold, Middlesex and the Dental Hospital of London; Harry Webb Robey, Charing-cross and the Dental Hospital of London; Arthur Lewis Rowley, Guy's Hospital, Dental Department, and School; William Albert Hodgins Saul, University College, Royal Infirmary, and the Dental Hospital, Liverpool; Frederick William Stanley Stone, M.R.C.S. Eng., L.R.C.P. Lond., St. Thomas and Guy's Hospital, Dental Department, and School; Ernest Stringfellow, Guy's Hospital, Dental Department, and School; Harold Tattersall, Middlesex and the National Dental Hospital; Wallace Atkinson Taylor, Westminster and the Dental Hospital of London; Duncan Powerscroft Tracy, Reginald Umney, Ernest William West, and Thomas Henry Wilkinson, Guy's Hospital, Dental Department, and School; Harry Winder, Charing-cross and the Dental Hospital of London.

21 gentlemen were referred to their professional studies; 20 for six months and 1 for one year.

UNIVERSITY OF CAMBRIDGE.—At the examinations for medical and surgical degrees, Easter term, the following candidates were successful:—

FIRST EXAMINATION.

Part I. Chemistry and Physics.—C. Akerman, Caius; A. E. Barclay, B.A., Christ's; G. F. Bird and H. J. D. Birkett, Trinity; W. F. Blandford, B.A., Peterhouse; M. B. Briggs, St. John's; J. R. Briscoe, H. Selwyn; A. D. Brunwin, Trinity; P. J. Burgess, B.A., Sidney Sussex; S. H. Clarke, Caius; R. M. Courtauld, Pembroke; Coventon, Trinity; G. Cowan, King's; W. L. Cripps, Trinity; A. H. Crossley, Clare; H. F. Curl, Christ's; H. H. J. Fawcett, Trinity; G. R. Footner, Pembroke; C. B. Goulden, Non-Collegiate; H. E. Graham, Jesus; S. L. Harke, Pembroke; G. H. Harper-Smith, Caius; E. T. Harris, Christ's; Hart, Sidney-Sussex; W. H. Hastings, Trinity; G. P. D. Hawker, B.A., Caius; F. A. Hepworth, St. John's; E. Higson, Magdalene; T. W. S. Hills, Downing; G. G. Hirst, Caius; H. F. Horne, King's; J. B. Irving and F. S. Jones, St. John's; H. M. Joseph, Trinity; A. S. Littlejohns, Caius; F. J. Lovett, Trinity; F. Lushington, Jesus; C. W. P. Moffatt, Clare; R. F. Moore, non-collegiate; W. H. Orton, Trinity; B. H. Pain, Emmanuel; O. V. Payne, St. John's; H. I. Pinches, Sidney-Sussex; J. N. Robins, Christ's; G. H. Snepley, St. John's; T. Somerville, Emmanuel; E. C. Sparrow, Trinity; J. M. Stenhouse, Sidney-Sussex; S. J. Steward, Downing; H. T. Thompson, Christ's; G. Thwaites, St. John's; C. F. O. White, Trinity; R. E. Whitting, King's; H. Wight, Sidney-Sussex; A. B. Wilson and N. Wilson, Pembroke; F. L. Woods, Caius; R. A. Worthington, Clare; and E. A. Wright, H. Selwyn.

Part II. Elementary Biology.—C. B. M. Aldridge, A. E. Barclay, B.A., and H. J. Beddow, Christ's; G. F. Bird and H. J. D. Birkett, Trinity; M. B. Briggs, St. John's; J. R. Briscoe, H. Selwyn; E. M. Brown, Pembroke; H. G. Brown, Emmanuel; P. J. Burgess, B.A. Sidney-Sussex; H. M. Clarke, Clare; S. H. Clarke, Caius; D. H. Collingham, King's; G. C. Compton, Caius; E. J. Cooper-Smith, St. John's; R. M. Courtauld, Pembroke; A. W. D. Coventon, Trinity; G. Cowan, King's; F. D. Crew, Emmanuel; A. H. Crossley, Clare; J. M. Cunningham, Trinity; H. A. Cutler, B.A., Clare; S. Dixon, Trinity; E. A. Ellis, Downing; C. H. J. Fagan, Caius; H. Falk, King's; H. H. J. Fawcett, Trinity; G. R. Footner, Pembroke; L. H. Frankenburg, Emmanuel; R. E. V. Hale and G. H. Harper-Smith, Caius; Everard Harrison, Trinity; R. N. Hart, Sidney-Sussex; A. F. Heald, non-collegiate; F. A. Hepworth, St. John's; W. R. Higgins, Caius; E. Higson, Magdalene; T. W. S. Hills, Downing; H. F. Horne, King's; W. E. Hume and W. F. Ingpen, Pembroke; F. A. G. Jeans, St. John's; S. C. Johnson, Trinity; F. S. Jones, St. John's; H. M. Joseph, Trinity; A. E. Kerr, Christ's; H. R. Lawrence, Pembroke; P. C. Lichfield, Trinity Hall; R. Luker, Pembroke; H. F. Marris, Caius; C. W. P. Moffatt, Clare; W. M. Mollison, King's; R. F. Moore, non-collegiate; W. H. Newton, Emmanuel; W. H. Orton, Trinity; H. B. Owen, Caius; B. H. Pain, Emmanuel; O. V. Payne, St. John's; H. I. Pinches, Sidney-Sussex; C. T. MacL. Plowright, St. John's; R. N. Poignand, Caius; T. Somerville, Emmanuel; E. C. Sparrow, Trinity; J. M. Stenhouse, Sidney-Sussex; S. J. Steward, Downing; R. Streatfeild, Queens'; H. T. Thompson, Christ's; W. H. Thresher, Caius; G. Thwaites and G. A. Ticehurst, St. John's; W. E. Weber, H. Selwyn; R. E. Whitting, King's; H. L. Whytehead, H. Selwyn; E. Wight, Sidney-Sussex; R. G. Wills, St. John's; C. D. Wilson, M.A., Corpus Christi; H. W. Wiltshire, Clare; and F. L. Woods, Caius.

SECOND EXAMINATION.

Part I. Pharmaceutical Chemistry.—B. L. T. Barnett, B.A., St. John's; F. M. Bulley, Emmanuel; R. Butterworth, B.A., Christ's; S. Child, B.A., Pembroke; R. A. Clapham, B.A., Emmanuel; G. H. Colt, Sidney-Sussex; W. F. L. Day, Caius; A. P. Day, Christ's; J. H. Donnell, Caius; T. L. Drapes, Sidney-Sussex; R. S. Drew and J. E. Frere, Pembroke; H. P. Gibb, Sidney-Sussex; J. G. Gubbins, Clare; P. Hardy, Trinity Hall; P. Harrison, B.A., Christ's; E. H. Harrisson, Clare; N. G. Harry, Jesus; W. N. Heard, B.A., W. N. Downing; F. C. Hepburn and W. H. Hills, Pembroke; C. D. Horsley, Caius; B. Hudson, Clare; G. C. Lawson, B.A., and W. E. Lee, Trinity; H. B. McCaskie, Caius; F. B. Manser, B.A., Peterhouse; O. May, St. John's; E. B. F. Molteno, Pembroke; W. E. Muil, B.A., Caius; C. H. W. Page, Corpus Christi; P. N. Panton, Trinity; W. E. Paramore, St. John's; C. A. W. Pope, Trinity; R. M. Ranking, Pembroke; R. H. Robbins, Trinity; N. O. Roberts, B.A., Christ's; Rocne, B.A., Queens'; C. T. Scott, Sidney-Sussex; F. E. Shipway, B.A., Christ's; H. C. Sidgwick, Clare; J. L. Timmins, B.A., Emmanuel; S. M. Toppin, Caius; A. C. Warren, B.A., Emmanuel; F. Whitaker, B.A., Trinity; W. M. Willoughby, B.A., Caius; A. F. R. Wollaston, B.A., King's; and H. G. K. Young, B.A., Emmanuel.

Part II. Human Anatomy and Physiology.—A. G. Bate, B.A., King's; F. H. M. A. Beckett, B.A., H. Selwyn; R. L. Bellamy, B.A., Downing; H. Bentley, B.A., St. John's; J. R. Bentley, Emmanuel; F. M. Boulton, B.A., Trinity; W. V. Braddon, Trinity Hall; A. H. Brehaut, B.A., H. Selwyn; C. de L. Carey, B.A., Emmanuel; F. J. Child, B.A., Christ's; E. M. Clark, B.A., Trinity; J. S. Clarke, B.A., Caius; Colyer, M.A., Catharine; G. L. Crimp, B.A., Caius; W. E. M. Ede, B.A., King's; F. P. Edwards, Downing; A. O. M. Fehrsen, B.A., Caius; W. M. Fletcher, M.A., H. S. Flook, B.A., and O. F. F. Grünbaum, B.A., Trinity; A. E. Hodder, King's; C. R. Howard, B.A., Pembroke; J. H. McAllum, M.A., Christ's; A. Martineau, B.A., Emmanuel; A. S. Mellor, B.A., King's; J. W. Mercer, B.A., Clare; C. H. Miller, B.A., Trinity; D. J. Morgan, B.A., St. John's; S. H. Nathan, M.A., Trinity; H. H. Riddle, Peterhouse; L. W. Roberts, M.A., Downing; G. Roper, B.A., Non-Collegiate; E. A. Ross, Trinity; B. B. Sapwell, B.A., Corpus Christi; C. A. St. J. Scott, B.A., and G. A. C. Shipman, B.A., Trinity; A. I. Simey, B.A., King's; A. T. Spanton, B.A., Trinity; C. Stiebel, Trinity Hall; E. J. D. Taylor, Caius; H. Wacher, B.A., St. John's; E. G. Wales, Downing; R. F. Williams, B.A., Caius; J. A. Wood, B.A., St. John's; F. E. Wood, Downing; and R. T. Worthington, B.A., Trinity.

THIRD EXAMINATION.

Part I. Barnes, B.A., Christ's; Boulton, B.A., Clare; Byles, King's; W. D. Chapman, B.A., Corpus Christi; H. N. Clarke, B.A., Trinity; Denyer, M.A., Queen's; Dore, B.A., and W. Eardley, M.A., St. John's; Fryer, B.A., Christ's; Garrood, B.A., St. John's; Glasier, B.A., Emmanuel; Glynn, B.A., Clare; W. D. Harmer, B.A., King's; Hart-Smith, B.A., and Hay, B.A., Gonville and Caius; Jordan, B.A., Sidney-Sussex; Kemp, B.A., Clare; Letchworth, B.A., Emmanuel; A. F. MacCallan, B.A., Christ's; H. F. Parker, B.A., Emmanuel; Pettinger, B.A., H. Selwyn; S. P. Pollard, B.A., Gonville and Caius; Powell, B.A., Emmanuel; S. B. Reid, M.A., St. John's; R. E. Sedgwick, B.A., Gonville and Caius; Sewell, B.A., Pembroke; C. C. Simson, M.A., and G. R. Slade, B.A., Trinity; Stacey, B.A., and F. W. Sumner, B.A., St. John's; Sutcliffe, B.A., Emmanuel; Talbot, B.A., King's; Tallent, B.A., and E. C. Taylor, B.A., St. John's; Thorp, B.A., Emmanuel; I. Ll. Tuckett, M.A., Trinity; Ware, B.A., Pembroke; W. K. Wills, B.A., St. John's; R. J. Willson, B.A., Emmanuel; and A. G. Wilson, B.A., Gonville and Caius.

Part II. Betteridge, B.A., Gonville and Caius; T. H. Brown, B.A., Pembroke; Byles, King's; Carter, B.A., Jesus; Corner, B.A., Sidney-Sussex; H. G. Deller, B.A., Trinity; A. B. Green, M.A., Downing; Gregory, B.A., St. John's; Harrisson, B.A., Magdalene; Heilborn, B.A., Gonville and Caius; Levick, B.A., Jesus; E. A. C. Matthews, B.A., Trinity; H. E. May, M.A., and F. A. Mills, B.A., Clare; Nalsh, B.A., Trinity; Prost, B.A., St. John's; Ransome, B.A., Gonville and Caius; Roberick, B.A., Emmanuel; J. E. Sandilands, B.A., Trinity; Sargent, B.A., St. John's; Hon. G. H. Scott, B.A., Trinity; and C. White, B.A., Christ's.

LITERARY INTELLIGENCE.—The following books based upon the new Pharmacopœia will be published by Messrs. J. & A. Churchill. The third edition of "Materia Medica, Pharmacy, Pharmacology, and Therapeutics," by

Digitized by Google

Dr. Hale White, physician to Guy's Hospital. This is now ready. A new work on "Practical Pharmacy," by Mr. E. W. Lucas, examiner in pharmacy to the Pharmaceutical Society; the work will be profusely illustrated and will contain a chapter on the Analysis of Urine; the publication will take place shortly. Also the twelfth edition of Beasley's "Pocket Formulary and Synopsis of the British and Foreign Pharmacopœias," brought up to date by Mr. J. Oldham Braithwaite. The seventeenth edition of Squire's "Companion to the British Pharmacopœia" will, it is hoped, be issued in September.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The Cavendish Lecture was delivered before this society at the Town Hall, Hammersmith, on June 24th, by Mr. Howard Marsh, Mr. H. P. Potter, President, being in the chair. Mr. Marsh took as his subject Growth as an Agent in (*a*) the Production, (*b*) the Removal, of Deformity, and illustrated his lecture by numerous specimens, diagrams, and photographs. After the lecture, which was a thoroughly able and interesting one, the members of the society in large numbers gathered at the annual conversazione. Here there was much to interest in the exhibits placed on the tables by many well-known firms of chemists, instrument makers, and others; and special mention may be made of the beautiful collection of bacteriological cultures and microscopic specimens shown by Mr. W. Severn.

THE CENTRAL LONDON OPHTHALMIC HOSPITAL.—At the Mansion House on June 16th a meeting in aid of this institution was held, when, in the absence of the Lord Mayor, Alderman Sir Joseph Savory, Bart., M.P., presided. The Chairman remarked that he believed everybody present was fully impressed with the needs and utility of this hospital, which was established 54 years ago, and at the present time was relieving about 11,000 patients every year. Since its origin in 1845 it had benefited no fewer than 400,000 persons.—Sir Dyce Duckworth (consulting physician to the hospital, approving of the scheme for rebuilding the hospital, moved a resolution pledging those present to secure by every means in their power liberal aid from all who sympathised with ophthalmic suffering.—This was agreed to and the secretary then announced subscriptions amounting to £637. £13,000 are still required, however, for the proposed work.

PRESENTATIONS TO MEDICAL MEN.—On June 23rd, on the occasion of the first presentation of medallions and certificates to the male and female members of the York Town and Camberley Branch of the St. John Ambulance Association, Mr. H. E. Rayner, F.R.C.S., L.R.C.P. Lond. of Camberley, was the recipient from the male class of a meerschaum pipe, with an inscription on a silver shield. At the same time Mr. A. T. Wooldridge, L.R.C.P. Lond., M.R.C.S. Eng., of Camberley, was presented by the female class with an inkstand, both were thank-offerings for gratuitous instructions on first aid.—Mr. Edward Ryan, M.B. Melb. of Nhill, Victoria, Australia, the medical officer of the Nhill Hospital, Victoria, has been entertained at a banquet by the inhabitants prior to his leaving for England.—Mr. Wm. Geo. Armstrong, M.B., Ch.M. Syd., D.P.H. Camb., of Bowral, New South Wales, has been presented with a handsome clock by the inhabitants on his leaving the district.—Last week the members of the Lydney Junction, Severn, and Wye Joint Railway Ambulance Corps presented Mr. Cyril Nelson Thomas, B.A., M.B., B.C. Cantab., with a gold-mounted umbrella as a mark of appreciation for his services as honorary lecturer.

THE METROPOLITAN PROVIDENT MEDICAL ASSOCIATION.—The Right Hon. Sir U. Kay-Shuttleworth, Bart., presided at a meeting of this association on June 16th, at 121, Sloane-street, when the annual report for 1897 was unanimously adopted. The report stated that the work of the institution has been steadily carried on and in some instances satisfactorily developed. Taken as a whole, however, the figures for 1897 do not show any general improvement on those of previous years. A really satisfactory advance has been made both at Woolwich and at Islington. Pimlico, too, shows a slight advance. One new dispensary has been opened during the year at Whitechapel. Altogether there are now 19 branches of the association, of which 14 are dispensaries and 5 medical clubs. There has been a falling-off in the list of ordinary donations and subscriptions, which, excluding the £1000 given by the Baroness de Hirsch and the grant of £300 from the trustees of the London Parochial Charities, amounted to only £289 9*s.* 6*d.* The Council state that their attempt to grapple with the difficulties connected with the medical treatment of the working classes has been very successful as far as the funds they have had to deal with have permitted and that their system could be largely extended at once if more support were forthcoming. The following figures show the branch statistics for the year 1897:—Number of cards, 10,525. Receipts—Members' payments, £4839; grants from council of the Metropolitan Provident Medical Association, £450; grants from Hospital Sunday Fund, £119; honorary subscriptions, &c., £206. Payments—Medical staff, £3062; dispensers, £824; drugs and dispensary sundries, £415; official salaries (secretaries, collectors, &c.), £485; rent, rates, taxes, &c., £746; postage, printing, stationery, &c., £117.

Parliamentary Intelligence.

HOUSE OF LORDS.

FRIDAY, JUNE 24TH.

The Sale of Poisons.

ON the motion of the Duke of DEVONSHIRE the House gave a second reading to the Poisons Bill introduced and promoted by the Government. His lordship explained that the object of the measure was to give to the public some protection against the indiscriminate sale of poisons beyond that which was already afforded by the Pharmacy Act. That Act dealt with certain poisons and imposed certain restrictions on the sale of those poisons. The chief restriction which the Pharmaceutical Society imposed was that the sale of the poisons was limited to persons registered by the Society. The list of poisons in the schedule might be extended, on the recommendation of the Pharmaceutical Society, by the Privy Council, and repeated applications had been made to the Privy Council to include certain other articles enumerated in the schedule to the Bill now before the House under the Pharmacy Acts. Amongst those articles was carbolic acid, which was largely used as a disinfectant. The other articles were butter of antimony, chloride of zinc and its solutions, cresylic acid, hydrochloric acid, nitric acid, sulphuric acid, sugar of lead and other salts of lead, preparations of carbolic or cresylic acid or their homologues used as disinfectants, and containing more than 10 per cent. of any of them, and substances sold for the purpose of poisoning insects or vermin. The Privy Council had always declined to include those articles in the schedule to the Pharmacy Act upon two grounds. The first ground was that of the inconvenience to which the public would be exposed if any additional difficulty were imposed in the way of obtaining these extremely necessary articles, and the second was the dislocation of the trade which would follow if the sale of the articles were placed in the hands of what was virtually a great monopoly. On the other hand, the Privy Council had received numerous representations from coroners' juries to the effect that some additional precautions ought to be taken against the indiscriminate sale of these articles. It was not contended that this legislation, or any other legislation, could very largely diminish the number of deaths which annually took place in consequence of the use of these articles. Out of 579 deaths which occurred in 1895 and 1896 owing to the use of the articles enumerated in the schedule of the Bill only 111 were due to accidental causes, 468 being cases of suicide. Of the 111 cases 29 were cases of children under ten years of age. There lordships would agree that if better protection could be given against the accidental use of poisons, it ought to be given. The Bill also contained a certain amendment of the Pharmacy Act itself. That Act had not been altogether successful in preventing accidental deaths from the use of poisons included in the schedule of the Act, for of 786 deaths which took place in 1895 and 1896 from the use of the poisons included in the schedule of the Act exactly half were the result of accidental use of the poisons. The Bill provided that the Privy Council might independently of the Pharmaceutical Society make regulations in regard to the sale of the poisons.

HOUSE OF COMMONS.

TUESDAY, JUNE 21ST.

The Indian Medical Service.

Captain NORTON asked the Under Secretary of State for War whether in connexion with coming changes in the Army Medical Staff it was in contemplation to withdraw the officers of the Army Medical Staff from the medical charge of Her Majesty's troops serving in India.—Mr. BRODRICK replied: No, sir; I am not aware of any such intention.—Captain NORTON asked the Secretary of State for India when it was proposed to amend the Indian Medical Regulations so as to insure that officers of the Indian Medical Service who have no previous military experience, or at all events have not any lengthened period of experience in military duties, shall be made to pass a longer period for military medical training than two months in the office of a principal medical officer prior to being selected for promotion to administrative grade; whether any changes and, if so, what changes in this respect had been proposed or recommended; and when they would be promulgated.—Lord GEORGE HAMILTON replied: I have not received from the Indian Government any proposal to amend the Indian medical regulations in regard to the training of medical officers selected for promotion to the administrative grade.

Admissions to Military Hospitals.

Captain NORTON asked the Under Secretary of State for War if he could state the number of non-commissioned officers and men annually admitted into hospital, the number discharged from hospital but

Digitized by Google

recommended for light duty, as well as the number of invalids discharged from the service, also the average number in hospital suffering from incurable disease.—Mr. BRODRICK replied that, including the army at home, in India, and at all other stations, the average number of admissions to hospitals during the last ten years was 198,735, but of these cases the great proportion would be unimportant in their character, and would not be regarded in an ordinary hospital as being of the in-patient class. Each admission of the same man was reckoned in the figures given as though it were a separate case: 2887 men had on the average been discharged as invalids. There were no records to show the number discharged from hospital but recommended for light duty or the number in hospital suffering from incurable disease.

THURSDAY, JUNE 23RD.

The Water Question.

At this sitting of the House there were four private Bills promoted by water companies in different parts of the country set down for consideration and in connexion with each of them Mr. Chaplin, President of the Local Government Board, had given notice of a series of new clauses which he proposed to have inserted. Mr. CHAPLIN introducing the subject, recalled to the House what had occurred at Maidstone, King's Lynn, Camborne, and other places, and said that the time had come when, in the opinion of the Local Government Board, some action was necessary. The Board addressed two circulars to all the different local authorities, the first inquiring by whom their water was supplied—whether by local authorities or by water companies—and the second impressing upon them the necessity of seeing that their supplies were pure and wholesome, and urging the responsibility which rested upon them in the matter. The Local Government Board did this early in the year and, in the meantime, various water Bills were delivered and received by them, in some of which there were included clauses to prevent pollution. These clauses, generally, were for the purpose of obtaining further powers of preventing pollution; but they differed in many ways and were open to objections and, although the Local Government Board agreed generally in the objects in view, they had to consider all the alternative proposals which could be made. But apart from the proposals in the Bills they had had complaints in certain cases of the quality of the water supplied by different local authorities and the views of the department with reference to the supply of pure and wholesome water and the means of preventing pollution were embodied in the reports which were sent to the committees to whom the Bills were referred. General clauses were drafted which should be applicable to all the Bills and these now appeared on the paper, though they had been modified to meet, as far as possible, the objections which were taken to them as originally drafted. In this, he had reason to believe, they had to some extent succeeded. As to the clauses themselves, he would point out that two conditions were essential to prevent as far as possible the recurrence of similar disasters to that which took place at Maidstone. The first was that the consumer must be protected against any shortcomings on the part of the water authorities and, secondly, these authorities themselves must be invested with sufficient powers to protect themselves from pollution of the sources from which they drew their supply. There was a third point which somehow or other appeared to have been overlooked in existing legislation. This was that the failure to fulfil existing obligations to provide a pure and wholesome supply of water was to be liable to a definite penalty. This was not the case now, but the matter was dealt with in one of the clauses he had put down on the notice paper. With regard to the other points endeavour was made to protect the consumer from any failure of duty by the water authority, first by empowering an officer authorised by the local authority to enter the premises of the water authority and take samples of the water supplied, and secondly by allowing consumers under certain conditions to take a similar course. Indiscriminate power of entry given to any consumer would entail needless annoyance on water authorities and therefore to the power of entry the following conditions were attached: that the consumer should obtain an order from a justice of the district granted only after reasonable notice given by the consumer to the water company of intention to make the application and upon showing reasonable cause for doing so; and, further, a notice of six hours would be required stating when and where samples were proposed to be taken. These conditions would secure the water authority against frivolous action on the part of a consumer. For the protection of water authorities against pollution of their sources of supply it was proposed to give to officers of the water authority or the medical officer of the local authority power to enter on lands or premises from which water was supplied and "to take and carry away samples of any water or of any matter, substance, or liquid which may appear likely to cause pollution to the water of the company or the sources of supply whereby such water may be fouled, and if the right of entry is obstructed or refused them a justice in the district after notice and reasonable cause may require admission by order." It had been objected that the clauses were unnecessary, and, if necessary, that they should be embodied in a public Bill; that the consumer should be eliminated from the clauses, and that the clauses should not in any case apply to corporations. Admitting the different position of corporations who supplied only their own constituents—these were but a small minority—the great majority of corporations supplied others, and he saw no valid reason for exempting them from the clauses. As to the elimination of the consumer it had apparently been forgotten that, in the Bill of last session dealing with the London water companies, the consumer was given power to take the water company before the new tribunal, and local authorities were empowered to assist the consumer with funds. It had been impossible, owing to pressure of business, to introduce these clauses in a public Bill, and with twenty-one water Bills before the House and in view of disasters such as he had mentioned, he was anxious to make some effort to improve the present position and this opportunity presented itself. This was a question directly affecting the public health, the need of reform could not be denied, there was nothing in the clauses to which reasonable objection could be taken, and he hoped the House would support him in the matter having regard to the useful and beneficial proposals which these clauses contained.—Mr. MELLOR, a former Chairman of Ways and Means, said that this was an attempt to alter the general law by means of a private Bill and as such it was bad legislation and should not be encouraged. He said this quite apart from the merits of the proposed clauses.—Mr. CORNWALLIS, the member for Maidstone, said that while his constituents were grateful to the President of the Local Government Board for what he proposed, they considered that his proposals did not go far enough and that the whole subject should be dealt with in a public Bill.—Sir JOSEPH PEASE also argued in favour of a public Bill.—Sir W. HART DYKE and Mr. BUXTON spoke in the same line.—After some further debate, in which several more members declared themselves in favour of a public Bill, Mr. CHAPLIN said he must yield to the evident sense of the House and withdraw his proposals.—The clauses were accordingly withdrawn.

The Dangers of Italian Ice-creams.

Sir HERBERT MAXWELL asked the President of the Local Government Board whether his attention had been drawn to recent deaths of children owing, as was alleged, to their having eaten so-called "ice-creams" sold by Italians in the streets; whether he was aware that several samples of these creams had been reported on by Dr. Klein, to the effect that all of them were swarming with colonies of the bacilli characteristic either of sewage matter or putrescence, or both; whether, in addition, attention had been drawn to the danger of mouth-to-mouth infection to children sucking ices successively out of the same glass; and whether the provisions of the Public Health Acts and the Food and Drugs Acts were inefficient to control or prohibit the sale of poisonous compounds such as these ices.—Mr. CHAPLIN replied: My attention has been drawn to this subject and I am aware of the fact that two children recently suffered from vomiting and diarrhœa after eating ice-cream, one of them dying, and that the coroner's jury attributed the death to the consumption of ice-creams. I understand that Dr. Klein in 1894 made some investigations for one of the London vestries of specimens of water and ice-cream submitted to him and that he discovered numerous organisms. As to the third question the practice referred to is obviously objectionable, but I have no evidence of actual mischief having resulted. I am advised that these ices would come within the provisions of the Public Health (London) Act, 1891, section 47, and also under the Public Health Acts Amendment Act, 1890, where that Act has been adopted; but I am making further inquiries into the circumstances of these lamentable occurrences, and if it should prove to me necessary I shall have to consider whether any, and what, alteration of the law may be desirable.—Sir HERBERT MAXWELL asked the right hon. gentleman whether these so-called ice-creams could be regarded as dairy products and the places where they were made inspected.—Mr. CHAPLIN replied that he should be sorry to regard these places in the nature of dairies, but there was no doubt from what he knew that the conditions under which the ices were prepared were discreditable and dangerous in the extreme.

The Preparation of Calf Lymph.

Mr. CHANNING asked the President of the Local Government Board whether the calves from which lymph would be taken for vaccination would be submitted to the tuberculin test and those calves excluded from use which were shown by the tuberculin test to be suffering from tuberculosis?—Mr. CHAPLIN replied: I have considered this matter and the proposal of the hon. member will be unnecessary, because I am making arrangements by which each calf from which lymph has been taken will be slaughtered and examined by a competent expert and no lymph will be issued from any calf until it has been ascertained and certified on post mortem that the animal is not only free from all signs of tuberculosis, but that it is also healthy in other respects.

Venereal Disease in Hong-Kong.

Mr. DUNCOMBE asked the Secretary of State for the Colonies whether he was aware that the Contagious Diseases Ordinances which were in force in Hong-Kong from 1858 to 1887 were repealed in opposition to the wish of the colony and that the repeal had been followed by a serious increase of disease, as alleged by the China Association in their memorial of Aug. 30th, 1897; and whether, in view of the recent augmentation of our forces in Eastern waters, he would reconsider the refusal to sanction the re-enactment of these ordinances conveyed in his letter to the association of Feb. 19th, 1898.—Mr. CHAMBERLAIN replied: I am aware of the facts referred to by the hon. Member, but I am not prepared to sanction the re-enactment of the Hong-Kong Contagious Diseases Ordinances. I am, however, conferring with the governor as to whether other measures can be adopted to check the spread of venereal diseases in the colony. The correspondence is not yet completed and when completed it will be laid before the House.

Post-mortem Examinations.

Mr. DAVITT asked the Home Secretary whether his attention had been directed to the proceedings of a medical gentleman in making a post-mortem examination on the body of one John Leonard, who died at Alfreton: was he aware that Leonard was attended by two qualified doctors before death and that a certificate of the usual kind, showing the cause of death, was given on May 9th; that on the same day, a few hours after the signing of this certificate, a medical practitioner in no way concerned in the case entered the room where the body lay and performed the operation referred to without any authority from the coroner or the friends of the deceased; whether such conduct was a violation of the law, and what steps did he propose to take to stop such unwarranted proceedings in future.—Sir M. WHITE RIDLEY replied: Yes, my attention was called to the case some weeks ago and I made inquiries. It appears that the examination was carried out by the son of the doctor, one of the two mentioned in the question who gave the certificate, and at his request, the medical man being of opinion that his judgment as to the cause of death required verification. The only friends of the deceased who were known at the time were the people with whom he lodged and they assented to the examination being made. I am advised that it is by no means clear that there has been any violation of the law.

Hospital Stoppages in the Army.

Mr. ARNOLD FORSTER asked the Under Secretary of State for War what would be the amount of the hospital stoppage in the case of soldiers who have accepted the new messing allowance when the medical officer has certified that the soldier is in hospital owing to illness or injury incurred by reason of the performance of his duty, and when the medical officer has not so certified; and by what amount the hospital stoppage in the cases referred to would exceed or be less than the stoppage in the case of soldiers who have not accepted the new messing allowance.—Mr. BRODRICK replied that the hospital stoppage

Digitized by Google

was normally 7*d.* a day and was applicable equally to those who had and those who had not accepted the new messing allowance. In cases where the disability was certified to be the direct result of military service the general officer might remit one half of the stoppage and he might remit the whole if the disability was due to an injury received at drill or manœuvres.

FRIDAY, JUNE 24TH.

Adenoid Disease in the Hanwell Schools.

Dr. FARQUHARSON asked the President of the Local Government Board whether his attention had been called to a report by Dr. Willcocks of the Charing cross Hospital, by which it appears that out of 82 children varying in age from three to sixteen in the barrack schools of Hanwell belonging to the Central London District, it was found that 30 were suffering from adenoid growths of the throat at the back of the nose and 23 from enlargement of the tonsils, while in 9 cases there was considerable enlargement of the tonsils, and in several cases a discharge from the ear with perforation of the drum of the ear; and whether he would direct an inquiry to be made by the Local Government Board with a view to the best being done for each individual child.—Mr. CHAPLIN: I have already given directions for an inquiry with regard to the cases of the children referred to. I may, however, say that Dr. Willcocks in his report distinctly says that the school life and surroundings of the children cannot be held responsible in any sense for the adenoid disease, the disease being prevalent among children in all classes of society.

MONDAY, JUNE 27TH.

The Water Question.

Mr. MARKS asked the President of the Local Government Board whether he intended to introduce early next session a Bill to ensure the supply by water companies of pure and wholesome water and otherwise safeguard the interests of water consumers, and if so whether the Bill would apply to all existing companies.—Mr. CHAPLIN replied: I am not in a position to make any statement as to the legislation which the Government may propose next session or the scope and the extent of any Bill they may introduce.

Cost of Hospital Treatment in the Army.

Captain NORTON asked the Under Secretary of State for War whether he could state the *per capita* cost of each sick soldier in hospital.—Mr. BRODRICK replied that there was no general statement of cost made for all hospitals, but a short time back the cost was worked out at a typical hospital and it was found that the cost per patient over and above his cost when on duty was about 1*s.* 8*d.* a day for items concerning the man himself, or 2*s.* a day if the cost of the medical officers were added.

The Royal Army Medical Corps.

Mr. POWELL WILLIAMS, in reply to Dr. Farquharson, said that the warrant constituting the Royal Army Medical Corps had been approved by Her Majesty and would be published in the Army Orders for July.

Army Nursing Sisters.

Captain NORTON asked the Under Secretary of State for War whether, seeing that an army nursing sister could retire at the age of sixty after from thirty to thirty-five years' service with a pension of £38 10*s.* a year, whereas an army schoolmistress could retire at the age of fifty after twenty one years' service with a pension of £45 10*s.* a year, he would state why there should be such difference between the treatment of these two classes; and whether he would consider the advisability of improving the conditions of retirement of army nursing sisters.—Mr. BRODRICK said that the facts of the case were not as stated in the question. An army nursing sister would receive after thirty years' service £35 a year, and if reported as having given special devotion to her duties might receive a higher pension up to a maximum of £50. An army schoolmistress would receive after twenty-one years' service £31 19*s.* 2*d.*, and after thirty years' service £45 13*s.* a year. The Secretary of State saw no reason to make any change in these conditions.

Vaccination in Scotland.

Mr. DALZIEL asked the Lord Advocate whether the Secretary for Scotland had received a representation from the Abbotshall Parish Council urging that any action in regard to the prosecution of parents who had declined to have their children vaccinated should be delayed until after the election of a new council which would shortly take place; whether the Local Government Board had intimated that, unless the council prosecuted within ten days the members of the council would be summoned before the Court of Session; and whether he could accede to the request of the parish council.—The LORD ADVOCATE replied: In answer to the first portion of the hon. Member's question the Secretary for Scotland informs me that he received a letter from the chairman of the Abbotshall Parish Council a day or two ago, but the letter does not state that it is written by desire of the council. In reply to the second portion, the Local Government Board did make the intimation referred to in strict conformity with the terms of the statute which regulates their procedure in such cases. The Secretary for Scotland cannot, as at present advised, undertake to interfere with the ordinary course of the law in cases of a first prosecution, though he does not propose to make any change in the existing practice not to insist for cumulative prosecutions for the same offence.

THE VACCINATION BILL.

PROCEEDINGS IN THE GRAND COMMITTEE.

The Grand Committee of the House of Commons on Law met on June 21st, when the debate on Sir Walter Foster's amendment was resumed.

Mr THOMAS BAYLEY said that it was evident from the speech of the President of the Local Government Board that he would be rather in favour of a conscience clause like the one proposed, only he was afraid that a great many parents who had no conscientious scruples would take advantage of it. This fear was not justified, for it was only a person with conscientious objections who would take the trouble and bear the expense which the proposal in the amendment entailed. In this matter the Government were treating vaccination as if it were a mathematical medical certainty, while as a matter of fact it was nothing of the sort. No responsible medical man would say that it was a mathematical medical certainty. The army was vaccinated and revaccinated, and, in fact, the medical authorities had full sway over the men in the matter of vaccination; yet, according to the Royal Commission, no fewer than 3953 revaccinated soldiers suffered from small-pox during the last twenty years, and of these 391 died from the disease. That was a larger proportion than the persons who died from small-pox in the same time in the town of Leicester. In the town of Gloucester they had 190 persons who had been vaccinated during the outbreak suffering from small-pox. He agreed with Mr. Gladstone in saying that the State was a bad nurse and he insisted that the State had no right to say to a parent that his child should be treated in a particular way. If there was no conscience clause then there was nothing for it but imprisonment for conscientious objection. Such imprisonment, in his opinion, was a disgrace to our civilisation and a disgrace to us as a nation and for that reason he hoped the Government would accept some compromise. If they did not then agitation would increase and the feeling against vaccination would grow stronger and stronger.

Mr. MONK said that his view of the amendment was that it struck a heavy blow at vaccination generally, inasmuch as it left vaccination optional. He would remind members of the Committee that the Royal Commission said in their report, "Nor are we prepared to recommend that the State should cease to require vaccination and trust entirely to the voluntary adoption of the practice." With this recommendation before them the Local Government Board could not propose that vaccination should no longer be compulsory. For the life of him he could not see why, at any rate, the State should not adopt the suggestion of Sir William Priestley and insist that the child should be vaccinated before going to school and becoming a source of danger to its fellows. Soldiers were vaccinated, and so also were certain of the civil servants, and he saw no reason why the same rule should not apply to children going to school.

Mr. J. BRIGG, speaking in support of the amendment, gave an account of the experience of Keighley, where, he said, great good had been obtained from isolation.

Mr. J. W. WILSON said he intended to support the amendment and to do so in the interests of vaccination. He believed that the objection to vaccination was far more deeply rooted in the minds of the working classes of this country than the Government imagined, and that by the adoption of this amendment something would be done to overcome the objection.

Dr. CLARK also supported the amendment. He declared that the speech of the President of the Local Government Board showed that the department had learned nothing and had forgotten nothing in connexion with this subject. It had consented to the appointment of the Royal Commission and now it refused to accept one of its principal recommendations. Compulsory vaccination was established in this country on the theory that vaccination was a thorough and complete prophylactic, but at the present time no man of science in this country or even in Germany would stand by the theory, and he claimed that in the circumstances of the situation they should give a trial to a conscience clause. In our small-pox hospitals nine-tenths of the patients were people who had been vaccinated and revaccinated. He had no sympathy with the ignorance that underlay a great deal of the agitation against vaccination, but at the same time he could not shut his eyes to the fact that vaccination was only a partial prophylaxis, and that isolation was the thing to look to in this matter.

Mr. JOHNSON-FERGUSON submitted that in the interests of the dignity of the law they should have a conscience clause.

Mr. BRYN ROBERTS also spoke in support of the amendment.

Mr. T. W. RUSSELL, Parliamentary Secretary to the Local Government Board, said that all the material before the Board went to show that the men who really objected to vaccination were a small body while the careless and indifferent parents were to be counted by tens of thousands. In the case of Gloucester, which was practically unvaccinated when the outbreak occurred, no fewer than 27,000 persons rushed to be vaccinated when the small-pox got a grip of the town, while in the case of Cheltenham 7000 persons were vaccinated at the instance of the town council. Altogether he submitted that far too much had been made of the conscientious objector.

Mr. HELDER argued that this amendment meant the repeal of all the vaccination laws.

Sir WALTER FOSTER then replied to the debate. He said that the Committee must deal with things as they found them and recognise that there was a strong feeling in the country against vaccination; not only so, but they must pay regard to the recommendation of the Royal Commission. As to the position of Sir William Priestley he pointed out that there were four medical men on the Committee and Sir William Priestley was the only one of the four who objected to the amendment. To have only one penalty and then give the defaulter the opportunity of making a statutory declaration would not meet the case, because a single penalty would do all the mischief in the way of creating martyrs and stimulating agitation. As to the case of Barton Regis it was manifest that the conditions there were all in favour of an evasion of the law, while the system he proposed was full of safeguards to test the sincerity of the objector.

The Committee then divided, when 24 members voted for the amendment and 26 voted against it.

The amendment was consequently lost.

Mr. CHANNING moved to insert in the clause these words, viz:—"Notwithstanding any regulation of any lying-in or other hospital or infirmary, or other similar institution, the parent of any child born in any such institution shall not be compelled, under such regulation or otherwise, to cause or permit the said child to be vaccinated at any time earlier than the period after birth specified in this section."

Mr. CHAPLIN accepted the amendment and the words were inserted in the clause.

Mr. CHANNING moved to strike out the subsection providing for domiciliary visits on the ground that it involved compulsion on the parent and interference with his rights.

Sir WILLIAM PRIESTLEY said that the system of domiciliary visits had been recommended by the Royal Commission and had worked successfully and harmoniously in Scotland.

Sir CHARLES DALRYMPLE spoke in the same line.

Mr. CHAPLIN assured the Committee that the subsection was conceived in the interest of the parents and their convenience and that they would not suffer in an way from it. There was no compulsion, for the officer merely offered to vaccinate.

Sir WALTER FOSTER said that later he would move the insertion of

Digitized by Google

words to provide that where the home of the parent was unsuitable for the operation the vaccination should be performed elsewhere.

Mr. LOGAN condemned the subsection as dictating to the parent and interfering with his liberty.

The amendment was rejected by 26 to 6 votes.

On the motion of Sir WALTER FOSTER the specified period in the subsection was reduced from 9 to 4 months after the birth of the child.

Thereafter the Committee adjourned.

The Grand Committee of the House of Commons on Law met on June 24th, with Sir HENRY CAMPBELL BANNERMAN in the chair, and resumed the consideration of the Vaccination Bill.

Discussion was continued upon Section 3 of the first clause, which sets forth that if a child is not vaccinated within four months (nine months was the period mentioned in the Bill as introduced) the public vaccinator of the district shall visit the home of the child and shall offer to vaccinate the child with glycerinated calf lymph.

Mr. CHANNING moved to insert a provision for at least twenty-four hours' notice of the proposed visit of the public vaccinator.

Mr. CHAPLIN agreed that notice should be given, but he thought it was a matter that might be left to the Local Government Board to deal with by way of regulation.

Sir WALTER FOSTER said that the regulations of the Board did not always give satisfaction, and without saying that the dissatisfaction was well- or ill-founded, he thought in the circumstances it would be a good thing to insert in the Bill itself a proviso with regard to notice.

On the understanding that Mr. Chaplin would deal with the matter during the report stage of the Bill the amendment was withdrawn.

Dr. CLARK moved to delete the words, "with glycerinated calf lymph." The hon. Member argued that scientific investigation had not placed it beyond all doubt that this particular kind of lymph was absolutely free from the danger of communicating such other diseases as tubercle and erysipelas. In their report the Royal Commission on Vaccination said that further scientific investigation was obviously necessary, and so far as he was aware no such investigation had taken place. In these circumstances he thought the Government were not justified in inserting in the statute that glycerinated calf-lymph shall be used in the vaccination. His own idea, he said, was that there should be some option in the matter.

Mr. CHAPLIN opposed the amendment. The mover of it, he said, was quite mistaken in thinking that there had been no further scientific investigation into this matter of the lymph since the Royal Commission made their report. On the contrary, investigation had been carried on and was even now being carried on and the results made it perfectly clear to his mind that there was no danger either of tubercle or erysipelas being communicated by glycerinated calf-lymph.

Mr. CHANNING, supporting the amendment, said that the Royal Commission had established beyond doubt that calf-lymph had been the cause of serious illness and even death and it had not yet been proved that the addition of glycerine prevented these results.

Sir WILLIAM PRIESTLEY gave an account to the Committee of certain experiments with glycerinated calf-lymph which he had himself seen, saying that they furnished remarkable evidence of the power of the solution of glycerine to destroy the organisms of disease which might go along with the calf lymph, without impairing the efficacy of the lymph itself. In his opinion this was the best form of lymph that could be offered to the public, though he quite admitted that in course of time science might improve upon it.

Sir WALTER FOSTER said that to take away these words as had been proposed would be to deprive the Bill of its only merit. Not only so, but he regretted that the question had been raised, for the discussion which had taken place would, he feared, do a great deal to disturb public confidence in vaccination and in glycerinated calf-lymph.

Mr. CARLILE said he had prepared an amendment in which it was proposed that if the parent signified a desire to have the vaccination performed with humanised lymph the public vaccinator might so perform it on receiving a written statement of the desire of the parent signed by the parent and witnessed by one witness. This, he said, represented a compromise which perhaps Dr. Clark might accept.

Dr. CLARK said he was willing to accept this suggestion, for his only object was to give parents an option in the matter.

Mr. J. W. WILSON pointed out that in course of time some other form of lymph might be discovered, and suggested that the provision in the Bill should be to the effect that the vaccination shall be performed with glycerinated lymph or any other form of lymph the Local Government Board might issue.

Mr. CHAPLIN expressed his readiness to accept this suggestion if it commended itself to the Committee generally, though he was afraid some Members had no very great confidence in the Local Government Board. As to there being an option, he might say that one existed already, because it was perfectly open to any parent to employ a private practitioner, and in that event any lymph could be used.

Mr. BAYLEY said that a great many people would feel horrified at the idea of their children being vaccinated with lymph taken from a dead animal and asked the President of the Local Government Board for an assurance on the subject.

Mr. CHAPLIN replied that in no circumstances whatever would lymph be taken from a dead animal or would any be imported from abroad. All the lymph which would be used by the public vaccinators would be produced, prepared, and issued by the Local Government Board and it would be ready in ample time for the passing of the Act.

The amendment moved by Dr. Clark was then withdrawn and words incorporating Mr. Wilson's suggestion were inserted in the section.

Mr. CHANNING moved to insert words providing that the lymph shall be "free from blood and extraneous micro-organisms or ptomaine alkaloids and certified to be absolutely free from the risk of causing any disease other than cow-pox, such certificate to be produced and a copy thereof to be supplied on demand of the parent."

This amendment was opposed by the Government and rejected by the Committee by 14 to 5 votes.

Mr. CHANNING, on behalf of Sir WALTER FOSTER, moved to add the two following sections to the clause—viz.: "The public vaccinator shall not vaccinate a child if, in his opinion, the condition of the house in which it resides is such that it cannot be safely vaccinated. A public vaccinator may give a certificate under Section 18 of the Vaccination Act of 1867 of postponement of vaccination on the ground that the house in which the child resides is in such a state that the child cannot be safely vaccinated, and shall forthwith give notice of any such certificate to the medical officer of health for the district."

This amendment was adopted by the Committee.

Mr. BRIGG moved to add these words: "But no child shall be vaccinated whose parents, or the person in charge of the child, shall at the time allege reasons which to the public vaccinator are considered by him sufficient to justify him in postponing or refusing vaccination."

Mr. CHAPLIN opposed the amendment as unnecessary, saying that under the present law there was power to postpone vaccination for sufficient reason, and the Committee rejected it by 18 to 8 votes.

The question was then put from the chair that Clause 1 as amended stand part of the Bill and upon this there was some general discussion with regard to the merits of the clause.

In the end the clause was adopted by 20 to 7 votes.

The Committee thereafter adjourned.

The Committee resumed consideration of the Bill on Tuesday June 28th, with Sir H. CAMPBELL-BANNERMAN in the chair. Clause 2, which runs as follows, was taken in hand: "An order under Section 31 of the Vaccination Act of 1867, directing that a child be vaccinated, shall not be made on any person who has previously been convicted of non-compliance with a similar order relating to the same child."

Mr. THOMAS BAYLEY moved that a vaccination order should not be made until the sanction of the Poor-law guardians had been obtained. Without this alteration, he contended, the Bill would take from the guardians the power they practically possessed of deciding whether vaccination should be compulsory or not.

Mr. LOGAN called upon every member who respected local self-government to vote for the amendment.

Mr. T. W. RUSSELL preferred the clause as it stood.

Mr. CHANNING invited the Government to reflect that according to the Royal Commission the Local Government Board had always been beaten in conflicts with the guardians over vaccination.

The Solicitor-General (Sir R. FINLAY) hoped the Committee would not accept the amendment, which was revolutionary, because it would nullify not merely the clause but an existing law. It might surprise some people to learn that under the law as it stood a vaccination officer could take proceedings without reference to the guardians. That was made clear in the case of Braddon *v.* Low. The Bill offered the substantial concession that there should be only one conviction under Clause 31 of the Act of 1867 and the Government could not go further.

Mr. BRIGG thought the Solicitor-General showed how little he understood the position of anti-vaccinationists. He stamped on their toes with his law, forgetting that in practice the guardians possessed some option with regard to compulsion. That option would be taken from them if the amendment were not adopted.

Mr. HAZELL hoped the amendment would not be pressed as it would raise discussions among guardians not hitherto agitated by the vaccination controversy.

Sir WALTER FOSTER thought Mr. Hazell mistaken. Anti-vaccinationists were summoned for the first time without their cases being discussed by the guardians. The working of the Bill would only agitate the latter when vaccination was enforced contrary to their wishes. That, however, was a serious contingency. It involved, moreover, an intolerable position for the vaccination officer, on one side of whom would be the Local Government Board, determined that he should vaccinate, and on the other the guardians perhaps bitterly hostile. It was true that the power to vaccinate against the wishes of the guardians had existed for many years, but it had been in abeyance and its resuscitation might provoke very unfortunate contests. He hoped, therefore, that the amendment would be adopted.

The amendment was rejected by 17 votes to 11.

Colonel LONG pointed out that although a person who objected to vaccination would escape a second prosecution under Section 31 of the Act of 1867 he would be liable under Clause 29. He therefore proposed to remove the latter liability, though he regarded anti-vaccinationists as the victims of mistaken views.

Mr. J. W. WILSON appealed to the Government to assent to the amendment for the sake of consistency, their own profession being one of desire to save non-vaccinationists from repeated penalties.

The SOLICITOR-GENERAL, opposing the amendment, assured the Committee that persons convicted under Section 31 were never prosecuted under Section 29.

The amendment was negatived by 16 votes to 14.

Sir WM. PRIESTLEY moved to insert the words "As hereinafter provided," his purpose being to propose when the occasion arises the following consequential provision: "No proceedings under Section 31 of the Act of 1867 shall be taken against any person who has been convicted under Clause 29 on account of the same child until it has reached the age of five years, and if at that time the person in charge of the child still objects he shall make a statutory declaration of his objection and thereupon no order shall be made or proceedings taken with reference to the non-vaccination of the same child." Sir William Priestley thought this might be regarded as a reasonable concession to the anti-vaccinationists. When a child reached the age of five years the objection of the parents to vaccination might have ceased, especially as it might be thought that a five-year old child would bear the operation more easily than an infant; moreover, during the first five years of life the danger from small-pox was incurred chiefly by the family, but afterwards it was one for the whole community, because children five years old were often ready to go to school. This fact was made clear at Gloucester. Children caught the small-pox at school, whence it spread like a great conflagration. He offered his amendment as a compromise, being so anxious to prevent small-pox that he would willingly conciliate opposition if he could.

Mr. CHAPLIN could not agree to the amendment, which would not, he believed, conciliate opposition.

The amendment was, however, carried by 17 votes to 12, the consequential provision being left for future consideration.

Mr. LOGAN moved that there should be only one prosecution in a family instead of one for each child.

Mr. CHAPLIN resisted the proposal as likely to increase the number of unvaccinated children.

Sir WALTER FOSTER did not believe that prosecutions promoted vaccination. Every man so treated made twenty converts against the law. He went about as a missionary. If he were imprisoned he was met on his release by a brass band and held up as a man suffering from what was called an infamous law. He (Sir Walter Foster) thought these agitations detestable. He did not want them to occur and he believed the amendment would help to stop them.

The amendment was rejected by 15 votes to 12, after which a proposal by Mr. BRIGG that the fine for resistance to vaccination should

Digitized by Google

not exceed 5s. including costs (instead of 20s.) was negatived by 18 votes to 17. Clause 2 was then added to the Bill.

Clause 3 reads: "The Local Government Board shall have the same powers of making rules and regulations with respect to public vaccinators (whether under contracts made before or after the passing of this Act) as they have with respect to vaccination officers, and any rules or regulations made by the Board with respect to vaccination, whether under this or any other Act, shall while in force have effect as if enacted by this Act."

Mr. CHAPLIN, explaining that the form of the clause had given rise to ungrounded suspicion, proposed to change it to the following:—"The Local Government Board may make rules and regulations with respect to the duties and remuneration of public vaccinators, whether under contracts made before or after the passing of this Act."

A discussion as to whether this proposal should not be postponed till the next sitting lasted till the Committee rose.

Appointments.

Successful Applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ALCOCK, R., M.B., Ch.B. Vict., has been appointed an Assistant Honorary Surgeon for the North Staffordshire Infirmary.

ANDERSON, F., M.B., M.S. Edin., has been appointed a Resident Medical Officer for the York Dispensary.

ASHTON, GEORGE, M.B., Ch.B. Vict., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Assistant Medical Officer for the London County Asylum, Claybury.

BAIGENT, WILLIAM, M.D. Durh., B.S., has been appointed Medical Officer of Health by the Northallerton Urban District Council, vice C. Tweedy, resigned.

BOWMAN, C. CLARK, L.R.C.P. and S. Edin., has been appointed a Medical Referee under the Workmen's Compensation Act for the County Court Districts of Alnwick and Rothbury.

BROWNE, H. W. L., L.R.C.P., F.R.C.S. Edin., M.R.C.S., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for No. 85 County Court District, which includes Wolverhampton, West Bromwich, Dudley, and Walsall.

BURTON, C. G., M.R.C.S., L.R.C.P., has been appointed Resident Medical Officer for the North-Eastern Hospital for Children, Hackney-road, Shoreditch.

CANT, W. J., L.R.C.P. Lond., M.R.C.S., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for the County Court Circuit No. 17, which includes Lincoln, Gainsborough, Horncastle, and Market Rasen.

CLAYTON, W. K., M.D. Brux., L.R.C.P., L.R.C.S. Edin., of Wakefield, has been appointed a Medical Referee for County Court Circuit No. 14.

COSENS, WM. BURROUGH, L.R.C.P. Lond., M.R.C.S. Eng., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for the Dorset County Court Circuit No. 55 (the whole Circuit).

CUFF, ARCHIBALD, B.A., M.B., B.C. Cantab., F.R.C.S., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for the County Court District No. 13, comprising Sheffield and Rotherham.

EVANS, EVAN, M.B., D.P.H. Camb., F.R.C.S., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for County Court Circuit No. 31, Carmarthenshire, &c.

FOSTER, J. J., M.B., M.R.C.S., L.R.C.P., has been appointed House Surgeon for the North-Eastern Hospital for Children, Hackney-road, Shoreditch.

FREMLIN, H. S., L.R.C.P. Lond., M.R.C.S., D.P.H., has been appointed Senior Laboratory Assistant at the new Calf Lymph Establishment at the British Institution of Preventive Medicine, near Chelsea Bridge.

GROSVENOR, W. W., B.A. Camb., M.D. Dubl., has been appointed Physician for the Children's Hospital, Gloucester, vice W. M. Hope.

HAIR, ALLAN, M.R.C.S., L.R.C.P., has been appointed House Physician for the North-Eastern Hospital for Children, Hackney-road, Shoreditch.

HAMILTON, T., B.A., M.B., B.Ch., B.A.O. R.U.I., has been appointed a Medical Assessor for the Districts of Newport, Chepstow, Pontypool, and Usk, under the Workmen's Compensation Act.

HARDY, H. NELSON, L.R.C.P. Edin., F.R.C.S. Edin., M.R.C.S., of Dulwich-grove, S.E., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897.

HATTON, G. S., M.D. Durh., F.R.C.S. Edin., M.R.C.S., has been appointed a Senior Surgeon for the North Staffordshire Infirmary, vice J. Alcock.

HICKS, E. BULLER, JUN., L.R.C.S., L.R.C.P., L.F.P.S. Glasg., has been appointed Medical Officer for the Easingwold Union Workhouse, and District Medical Officer and Public Vaccinator.

HOPE, W. M., M.R.C.S., has been appointed Surgeon for the Children's Hospital, Gloucester, vice W. Washbourn.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1898, which was completed with the issue of June 25th, and the Title-page to the Volume are given in this number of THE LANCET.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1898 will be ready shortly. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance.

GYNÆCOLOGISTS IN FICTION.

THE June number of *L'Écho du Bien*, a journal of philanthropic and charitable work, devotes some space to a notice of a recent French novel, "Les Florifères," the authoress of which (for it is said to be written by "un bas bleu") has allowed her imagination to run riot in a morbidly fantastic way. One of the personages depicted in these pages is a medical man who is described as "ovariotomiste spoliateur d'ovaires de mondaines détraquées par la folie de la jouissance sans complication fâcheuse, type nouveau qui tend à se répandre dans une inquiétante proportion. Elles sont telles que certains arbustes créés par la culture moderne, aux admirables fleurs qui ne rapportent pas de fruits. Au milieu de ces mondaines florifères apparaît la silhouette du docteur Trajan, opérateur adoré de ses clientes, qui vit de leurs faiblesses, les exploite et les opère sans pitié; quant à lui il épousera une belle fille, saine et vigoureuse, de la province, pas florifère du tout et très fructifère, qui lui donnera de beaux enfants. C'est le type du gynécologiste mondain qu'on montre entre le diseur de monologues et la princesse à la mode. On aura son castreur comme on a son coiffeur et son pédicure, et le docteur Trajan mettra bientôt sur ses cartes de visites, en sous-titre, *opérateur de la Princesse X. et de la cantatrice Y.* La mode est à la stérilité, aux hanches amincies, aux tailles d'éphèbes souples et insexuées. On se fait débarrasser de ses ovaires, en une certaine classe, comme on se fait percer les oreilles."

"ANNUAL ERYSIPELAS."

To the Editors of THE LANCET.

SIRS,—Having had a similar experience to that mentioned by "M.B. and C.M." in THE LANCET of June 25th it may interest him to know the explanation of these occurrences which presented itself to me and the inferences I drew as to the most likely method of putting an end to the series—viz., that an attack of erysipelas in these patients only gives immunity for a period of something less than twelve months; that their dwellings and wearing apparel become thoroughly infected and that they are reinfected by them; and that the reinfection takes place either during the "clearing down" which occurs next after they cease to be immune or on their resuming the wear of those garments which they were using when the previous attack supervened. In the one case the attacks might probably occur at or about the "spring cleaning"; in the other at the time when summer garments are donned. At both of these epochs there is, I have reason to believe, ample opportunity of meeting with the predisposing chill. The inferences as to prevention are obvious—change or thorough disinfection of the residence, destruction of all infected garments which cannot be efficiently sterilised, and sterilisation of those which can.

I am, Sirs, yours faithfully,

Blackpool, June 27th, 1898. LEONARD MOLLOY, M.A., M.D. Dub.

JUVENILE TRAIN-WRECKERS.

ON June 19th two small boys, aged respectively nine and ten years, were charged at the North London police-court with trying to upset a train by placing a piece of iron and a piece of wood in the catch points. Evidence was given to the effect that in some places the wall which protected the line was so low that children could easily get over. Mr. D'Eyncourt ordered both the little urchins to be birched. The spread of education may be a very noble thing, but it does not seem to have much effect in softening the manners of the rising generation or in preventing them from being savage. The mere attempt to upset a train is such a very serious offence that it should be correspondingly severely punished, and in the case of an adult, whether it succeeds or not, it should certainly rank as manslaughter, even if it should not be considered a capital offence. But the "soaring human boy" must be appealed to through his sense of pain and there must be no sparing of the rod.

THE PAYMENT OF LOCUM TENENTS BY PUBLIC BODIES.

To the Editors of THE LANCET.

SIRS,—I have lately received notice from three public lunatic asylums of vacancies for locum tenents, each offering two guineas a week with board and lodging. It seems a curious contrast that a struggling general practitioner has to pay a locum not only three guineas a week, but also fares and frequently agents' fees, and the contrast does not reflect credit on the responsible asylum authorities. I hope that others will follow my example and refuse to accept such ridiculously small remuneration for what is to most men trying work. If smaller fees than usual are taken by the locum tenents let them favour the poor doctor and not the public bodies who pay their permanent medical officers highly. I am, Sirs, yours faithfully,

June 21st, 1898. LOCUM.

ROBINSON'S MENE TOWELS FOR LADIES.

WE have received samples of various sizes and qualities of towels for ladies' use made by Messrs. Robinson and Sons of Fann-street, E.C., and Chesterfield. They consist for the most part of absorbent cellulose wadding enclosed in gauze, with a layer of absorbent cotton in front and a thickness of waterproof wool on the back, the whole being sterilised by treatment with 1 in 2000 sublimate solution. Cellulose wadding has a high absorptive and diffusive power for liquids and even when thoroughly wetted is retained in shape by the other fibrous materials associated with it. No. 1 towel (the smallest) is about 9 in. long and is suitable for all ordinary cases; it is sold at the low price of 6*d.* per dozen. No. 2 and No. 3 are somewhat thicker and about 10 in. long; they are especially useful when travelling or when changing is inconvenient The prices of No. 2 and No. 3 are 1*s.* and 1*s.* 6*d.* per dozen respectively.

HUNTER'S PATENT AUTOMATIC GRIP AND SPLINT.

THIS instrument is used for the secure fastening of obstetric binders or wide bandages in general, allowing an easily controlled support or compression without the use of pins, straps, hooks, buttons, &c. It consists of a gently curved metal plate about 11 in. long and 1½ in. wide, pierced with a slot about 10 in. long, having a row of 26 sharp points projecting from each edge. The two ends of the bandage, after being drawn through the central slot and tightened as required

Digitized by Google

by pulling in opposite directions, are fixed by being pressed against the sharp points, which easily penetrate the material, and are then covered with a thin plate of flexible steel, so that there is no possibility of accidental contact with them. This fastener will obviously act somewhat as a splint in preventing the uncomfortable wrinkling up to which wide bandages are so liable. For obstetric purposes an ordinary strip of thin bleached cotton swansdown calico, the width of the slot in the grip, can be used for the binder over an ordinary towel folded to form the pad. It may also be employed for keeping large poultices, &c., comfortably in position. The grips can be disinfected by boiling when required. They may be obtained from any dealer in surgical instruments or from the patentee and manufacturer, B. Hunter, 22, Lancashire-road, Bishopston, Bristol. The price is 15s. 6d.

"THE ARTHUR JEFFARES BARLOW FUND."

To the Editors of THE LANCET.

SIRS,—Will you please acknowledge in THE LANCET the following donations to the Barlow Fund:—Per Dr. J. W. Moore—"A Sympathiser" (Putney), £2 2s. T. C. D., £1 1s.

I am, Sirs, yours faithfully,

June 27th, 1898. R. H. CAPPER.

THE INTERPRETATION OF AN AGREEMENT.

To the Editors of THE LANCET.

SIRS,—Do you or any of your readers who may have had a similar experience consider one has any redress under the following circumstances? A purchases from B a cash practice, with a verbal undertaking from B that he has an agreement with his assistant (who has carried on the practice entirely for some years) not to practise in the neighbourhood. For certain reasons the assistant was not retained by A, and instead of seeking other employment he takes a room on the same premises, and after an interval of three months opens a surgery a few doors away and solicits the patients, with the result that the practice purchased by A is practically valueless. On applying to the agent for the agreement A finds that the assistant was simply bound down for three months not to practise within a quarter of a mile. Is this a reasonable agreement and likely to stand if contested? Any comment on the above will be gratefully received by

Yours faithfully,

June 28th, 1898. EMPTOR.

MEDICAL REFEREES UNDER THE WORKMEN'S COMPENSATION ACT.

To the Editors of THE LANCET.

SIRS,—I beg to enclose you a copy of the *Llanelly Mercury* of June 23rd announcing the appointment of a local medical man as a medical referee under the Compensation Act of 1897. As a junior member of the profession, living in the same town, I may, perhaps, be allowed to observe that the method of announcing the fact, coupled with the insertion of the letter from the Home Secretary, scarcely reflects dignity upon the medical man in question, nor is it calculated to inspire the rest of his professional brethren with the necessary respect due to his office. I should hardly think either that the Home Secretary intended his letter for publication in local papers. I should be glad to have an expression of your opinion on this subject.

I am, Sirs, yours faithfully,

June 28th. NEMO.

*** We agree that the method in which the appointment has been made public by the *Llanelly Mercury* is unfortunate, but we do not see any evidence that the medical man desired the letter from the Home Office to be printed, and it seems impossible for lay papers to understand the forms of medical etiquette.—ED. L.

THE LATE DR. JAMES McGREGOR LAING.

WE have received from Dr. J. Pickett and Dr. Reginald Hartley a list of subscriptions which have been made to a fund for the widow of the late Dr. Laing. We shall publish the names next week.

THE VALIDITY OF A DEATH CERTIFICATE.

To the Editors of THE LANCET.

SIRS,—A few days ago I certified as the cause of death in a child eight months old as follows: "Primary: meningitis. Secondary: convulsions." On the presentation of the certificate at the Registrar's office the mother was questioned as to the child being insured and on replying in the affirmative was informed that no insurance office would pay on the certificate without an inquest and conducted her to the coroner's court, where she was interrogated and an inquest ordered. I should be obliged if you will inform me—(1) was not this certificate ample to satisfy the Registrar-General? (2) is it not usual to call a medical man to give evidence in such a case (I had no doubt at all as to the case and no suspicion that all was not right)? and (3) has the coroner a right to order an inquest over a medical man's head in this manner?

I am, Sirs, yours faithfully,

June 24th, 1898. PERPLEXED.

*** 1. No doubt the certificate would satisfy the Registrar-General. 2. We think the medical man should be called to give evidence. 3. In our opinion the coroner was quite within his rights, and we go further and say that he exercised a wise discretion. The insurance of infant life should be fenced around with every possible safeguard.—ED. L.

THE GARBAGE-MONGER.

ON June 23rd Herbert Clarkson was sentenced to three months' imprisonment, without the option of a fine, for exposing unsound meat for sale. He had previously been convicted of a similar offence. This is a righteous judgment. Clarkson's offence is absolutely unpardonable and we should like to see the law amended so as to make the crime of exposing unsound meat or the intention of selling it for food on the same level as attempted murder. People who try to foist unsound meat as food are really poisoners and should be treated as such.

"HOLY WATER AND INFECTION."

To the Editors of THE LANCET.

SIRS,—With regard to your note on this subject in THE LANCET of June 18th it may interest some of your readers to know that, according to the *Semaine Médicale* of April 13th, 1898, Professor Vincenzi has found quite a collection of microbes in the holy water of one of the most frequented churches of Sassari (Sardinia). It contained, among others, Löffler's bacillus. The identity of this microbe was proved by cultures and by inoculations and it is important to note that at that time four cases of diphtheria (one of them fatal) had been observed at Sassari. I myself have seen a tramp washing his face in the holy water of one of the fashionable churches of the West-end.

I am, Sirs, yours faithfully,

June 22nd, 1898. J. KEBER.

Questor.—The annual report of the British Medical Temperance Association gives the following information as to the numbers of medical men who are total abstainers and are connected with the Association:—

	Members.	Student Associates.	Associates.
England and Wales	294	116	2

Scotland	26	0	0
Total ... ...'	466	424	3

W. R. S. would have been justified, in our opinion, in refusing to answer the clergyman's questions, and we should like to hope that in doing so he would have received the general support of the house committee. This opinion is based on our correspondent's account, but it is difficult to conceive circumstances which could modify it. We do not print this letter, as the case might be recognised and a worse violation of professional confidence so be brought about.

Dr. J. G. Bailey.—A portable acetylene lamp would, we think, answer the purpose much better. There are several makers of acetylene apparatus in Blackburn, Manchester, and Liverpool.

Mr. Cholmondeley Webb will find the information which he requires in Mr. A. H. Tubby's work, "Deformities: A Treatise on Orthopædic Surgery."

Sigma.—British American Ball Nozzle Co., 3, Farringdon-avenue, E.C.

Mr. Charles Thomas is recommended to consult his medical man.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received: *Western Gazette, Isle of Ely Advertiser, Southern Times, Scotsman, Eastern Daily Press, Sheffield Telegraph, North British Daily Mail, Newport Advertiser, Times of India, Pioneer Mail, Boston Independent, Leytonstone Independent, Accrington Observer, Architect, Liverpool Daily Post, Agricultural Gazette, Builder, South Wales Daily News, Croydon Guardian, Western Morning News, Devon Gazette, Yorkshire Post, Alnwick County Gazette, Walsall Observer, Bristol Mercury, Salisbury Journal, Newcastle Chronicle, Leeds Mercury, Elgin Courant, Cambridge Independent Press, Worcester Echo, Citizen, Birmingham Gazette, Glasgow Herald, Morning Leader, Yarmouth Mercury, Jewish Chronicle, Herald of Wales, Manchester Guardian, Lancaster Guardian, Yarmouth Advertiser, Leicester Post, Sussex Daily News, Hampshire Advertiser, Somerset Journal, Kidderminster Shuttle, Southern Times, Chester Chronicle, Lynn Advertiser, Portsmouth Times, Bournemouth Directory, Sanitary Record, St. Paul's, Ceylon Observer, Coventry Herald, Warrington Observer, St. Mary's Hospital Gazette, St. Bartholomew's Hospital Journal, Local Government Chronicle, Mining Journal, Hertfordshire Mercury, City Press, Reading Mercury, Local Government Journal, Weekly Free Press and Aberdeen Herald, Surrey Advertiser, Cambrian News, Medical Gazette, Llanelly Mercury, Derbyshire Times, Monmouth Observer, Lancashire Daily Express, Evening Chronicle (Newcastle-on-Tyne), West Middlesex Herald, Bacup Times, Aston Times, Lydney Observer, Stowmarket Courier, &c., &c.**

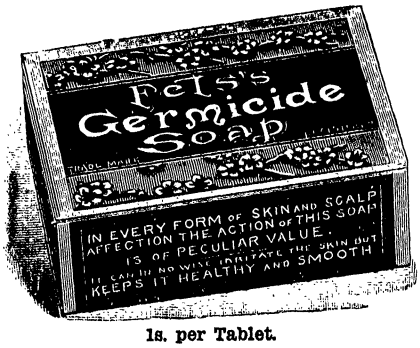
Winch. Quarts ,,	...	2/6 per lb.

"SYRUP HYPOPHOSPH. CO. LORIMER'S"

was introduced in reply to numerous inquiries by the Medical Profession for a preparation which should be at once elegant, of definite and stated formula, moderate price, and neutral or slightly alkaline.

From the BRITISH MEDICAL JOURNAL, January 22nd, 1898:—



"It is perfectly bright and neutral, and no trace of disagreeable odour; it is, in fact, a most excellent preparation. The composition and strength of the Syrup are shown upon the label."

From THE LANCET, January 22nd, 1898:—

"A very satisfactory preparation, of standard strength and quite permanent, absolutely neutral, and containing no deposit. May be relied upon as presenting in a most perfectly staple combination the ingredients of an excellent tonic formula."

1-lb. Bottles for Dispensing, 36s. doz.

All Chemicals, Drugs, Extracts, Liniments, Pills, Oils, Wines, Lozenges, Tinctures, &c., &c., Of the 1898 Pharmacopœia, made in our own Laboratories, and of guaranteed strength and purity.

1s. per Tablet.

A pure emollient and antiseptic soap, containing Hydrarg. Perchloridum, Ol. Eucalypti, Sal Alembroth, &c. Equally valuable as an application in Skin Diseases, for Surgical, Hospital, and Gynæcological use, or for toilet purposes. Quite a desideratum for those suffering from Eczema, Skin Irritation, and Parasitic Diseases, for Medical Practitioners, Surgeons, Midwives, Nurses, and Dressers. Its value as a Germicidal Agent in the treatment of Skin Diseases and for general purposes is fully established.

THE PERFECT CAPSULES.—Containing finest English Santal Wood Oil. Each tin contains full directions in four languages. 12s. per dozen tins of 36 Capsules each.

These Capsules are now in great demand, their composition being more EXACT than that of the Syrup itself, and there is no FREE Acid.

Fancy tin boxes of 24. Each Capsule = 30 mins. Syrup.

10s. 6d. Dozen.

CASCARA CAPSULES.

These are guaranteed to contain the equivalent of 30 mins. Fluid Extract. Prepared from the finest bark obtainable; they will not shrink.

Fancy round tins of 24, 7s. 6d. dozen.

FULL PRICE LISTS ON APPLICATION.

The Croonian Lectures

ON

THE CHEMICAL PRODUCTS OF PATHOGENIC BACTERIA CONSIDERED WITH SPECIAL REFERENCE TO ENTERIC FEVER.

Delivered before the Royal College of Physicians of London on June 14th, 16th, 21st, and 23rd, 1898,

BY SIDNEY MARTIN, M.D. LOND., F.R.S.,

FELLOW OF THE COLLEGE; PROFESSOR OF PATHOLOGY, UNIVERSITY COLLEGE; AND ASSISTANT PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND TO THE HOSPITAL FOR CONSUMPTION, BROMPTON.

LECTURE IV.[1]

Delivered on June 23rd.

THE ACTION OF THE POISONS OF THE TYPHOID BACILLUS, GÄRTNER'S BACILLUS, AND THE BACILLUS COLI COMPARED WITH THAT OF ALLIED POISONS.

MR. PRESIDENT AND GENTLEMEN,—There are two poisons which are not the products of bacterial action, being found in the seeds of plants, and which are of great interest in connexion with the toxic products of the three bacilli which have been examined. These poisons are ricin, obtained from the seeds of the castor-oil plant, and abrin, obtained from the seeds of the Abrus precatorius. The latter is used by the natives in India in the poisoning of cattle and its symptoms are those of a general toxæmia. Both these poisons produce conjunctivitis when applied to the eye and injected under the skin they cause diarrhœa with great general prostration. In an investigation I conducted some years ago I found that the two proteids present in the seeds of the abrus—viz., the globulin and the albumose—were both poisonous and that they produced similar symptoms. In one experiment a pigeon, weighing 216 grammes, received 0·2 gramme of abrus globulin, and death followed in six hours and was preceded by an increase in the number of respirations and a great lowering of the temperature, the total fall being 23·8° F. or 12·6° C. In another experiment a pigeon weighing 335 grammes received 0·02 gramme of the abrus albumose. The symptoms began in 4½ hours and the animal died in about 6 hours. There was a more or less continuous fall of temperature, and, unlike the first animal, the number of respirations per minute fell instead of rose. In the rabbit abrin produces, like the poison of the typhoid bacillus, a rapid fall of temperature and death. The fact that the abrus proteids produce diarrhœa, which is most commonly bloody, is remarkable. This is associated with the signs of a hæmorrhagic gastro-enteritis, there being great inflammation of the mucous membrane of the intestine and especially of the adenoid patches. The abrus poisons are very sensitive to heat, the action of the globulin being completely destroyed by the momentary raising of the temperature of its solution to 75° or 80° C. and that of the albumose at a rather higher temperature—viz., 85° C. What property it is of the proteid which has this toxic action—whether it resides in the proteid itself or whether there is some toxic body, possibly of a ferment nature, attached to the proteids—it is impossible to say; but the similarity of their action to that of the toxic products obtained from the closely allied micro-organisms—the typhoid bacillus, the Gärtner's bacillus, and the bacillus coli—is remarkable. No doubt in all these cases the effect on the intestine occurs during the excretion of the poison by the mucous membrane in whatever way it may be introduced into the body. The diphtheria poison sometimes produces diarrhœa when given in sufficiently large doses—a result which I never obtained from the injection of even large doses of the albumoses of anthrax or of ulcerative endocarditis—and this is also not an effect which is noticed as a result of the action of the tetanus poison.

With regard to the diphtheria poison the effect of different doses on the temperature and on the body condition is seen in the following experiment. A mixture of the albumoses and toxin was used and in the first experiment 2 c.c. were injected into the marginal vein. This was followed by some rise of temperature on the same day and on the next day weakness in the hind legs and a rapid fall of temperature to about 96° F. occurred, ending in the death of the animal. In another experiment when 5 c.c. of the same poison was given there was a great rise of temperature; the animal died during the night. Neither animal showed any diarrhœa or intestinal symptoms and the general effects were in marked contrast to the effects of the poisons in the three bacilli investigated.

The effect of the diphtheria poison in reducing the temperature of the body is also shown in another experiment in which a mixture of the albumose and toxin, which had been dried, was given. Altogether 0·2 gramme of this powder was injected into the marginal vein. After the first injection there was scarcely any rise of the body temperature, but the next morning the temperature had fallen 3° and a second injection of a small dose still further increased the depression of temperature, the animal dying in 24 hours. The fact, therefore, of a bacterial poison reducing the body temperature is not limited to the three bacilli which we have investigated, although it is a prominent feature of the action of their products. The diphtheria poison is readily affected by heat; thus in one experiment it was seen that after heating to about 60° C. for one hour the injection of 5 c.c. solution of toxin produced not a rise but a fall of temperature, and this was followed by a slight reactionary rise to the normal, after which the animal recovered and showed no symptoms. In another experiment, however, 5 c.c. of diphtheria toxin, heated for ten minutes at 60° C., produced a continuous but gradual fall of temperature up to the time of death on the fifth day of the experiment. Comparing this with a similar experiment in which the same dose—unheated—was given to another animal of the same weight, it was seen that the temperature rose somewhat after the injection and the animal died on the following night. The heat had therefore weakened the action of the toxin and this weakened toxin, instead of producing a rise of temperature, produced a continuous fall, an interesting result when compared with the effects of the products of the three bacilli. It may be concluded that a small dose of the toxin or a weakened toxin may produce a fall of temperature and no other change and that a larger dose of the toxin may produce a rise of temperature followed by a fall which precedes death or it may in some cases be recovered from; and that a large dose of poison may also produce a sudden and rapid fall of the body temperature, ending fatally in a few hours.

The effect of the diphtheria poison in producing a palsy dependent on degeneration of the peripheral nerves and that of the tetanus poison in producing convulsions is in marked contrast to that of the products obtained from the three bacilli, inasmuch as there was no evidence of palsy in any of the animals, even if they lived three weeks or longer, and no evidence of any convulsions. The effect of the abrus poisons on the respirations is well marked, producing in some cases, as has been shown, a rise in the number of respirations, and sometimes a fall, though in both cases the temperature persistently falls. The diphtheria toxin also has a profound effect on the respiratory system. A monkey weighing 1575 grammes received intravenously on successive days two doses of diphtheria albumoses, each of 0·3 gramme. After the first injection there was a depression of the rectal temperature, followed by a rise to a little above the normal, and afterwards, as well as following the second injection, the temperature became irregular, although not very high, until the end of the ninth day of experiment, after which it was normal. The respiratory curve showed, however, a greater irregularity. After the first injection there was a rapid rise in the number of respirations until they were nearly 80 a minute. Afterwards they fell, but following the second injection there was a gradual rise and the respiratory curve remained irregular until about the ninth day, when it fell to about 40 a minute. The effect of the injection of this poison on the general condition of the body was remarkable. After the first dose there were no general symptoms, but in 3 hours after the second dose the animal became progressively weaker, so that in 7 hours it could not sit up or move its arms and legs. There was complete motor palsy of the limb

[1] Lectures I., II., and III. were published in THE LANCET of June 18th and 25th, and July 2nd, 1898, respectively.

Digitized by Google

and trunk muscles but no respiratory paralysis and no palsy of the facial muscles, as the animal, lying on one side, with food within reach of its mouth, ate vigorously and swallowed perfectly. No knee-jerks were obtainable and no reflex on pinching the limbs. This condition lasted for over 24 hours after the second injection and in 26 hours the animal could sit up, but there were still no knee-jerks. These reappeared on the second day following the injection, and recovery from the motor and sensory palsy was complete on about the same day. The animal gradually and completely recovered and remained quite normal for several months, when it was killed. It may be remarked, in passing, that the features of the palsy were those of a complete suspension of the functions of the spinal cord.

Like diphtheria toxin tetanus toxin acts on the spinal cord, but in another direction: it produces convulsions instead of paralysis, and it produces this effect not only in the higher animals but in rodents. The diphtheria toxin does not affect the spinal cord in rodents. It produces a well-marked and universal degeneration of the peripheral nerves in the manner I have elsewhere described. The tetanus poison also to some extent acts on the peripheral nerves, inasmuch as I have found in animals which have received a small dose of the poison and which have survived for some time distinct degeneration in a few branches of the anterior crural and in the phrenic nerves. The degeneration is, however, extremely slight and is not sufficient to cause signs of paralysis during life. A special action on the cerebral hemispheres is to be ascribed to the anthrax products, and especially to the alkaloidal body, inasmuch as they produce stupor ending in coma which may either be recovered from or—as is more usual—end in death.

Action on the heart muscle.—In previous papers I have shown that it is a characteristic of the action of the albumoses of anthrax and of ulcerative endocarditis, as well as of the diphtheria poisons, to produce a well-marked fatty degeneration of the cardiac muscle, and this is as marked in the case of the anthrax albumoses as it is in the case of diphtheria poison. The poison of the typhoid bacillus produces the same result, although not to such a marked extent. In those animals which died slowly some change in the heart muscle was almost constantly observed; sometimes, however, it was absent. In none of these animals was there any degeneration of the peripheral nerves discovered, though branches of the anterior crural and phrenic nerves were frequently examined after staining in osmic acid. The actions of these poisons on the heart is therefore one independent of any action on the nervous system and is probably a direct toxic effect on the cardiac muscle. All the bacterial poisons which I have myself examined produce a profound change in the general nutrition, which is in many instances independent of any fever produced, and it may be that the degeneration of the heart muscle is only an expression of this disordered nutrition. Degeneration in the skeletal muscles, however, is not found. The structural changes which occur in the organs are the result of the action of these poisons—a subject which has been worked out very fully by Dr. Simon Flexner.[2]

CHEMICAL NATURE OF BACTERIAL POISONS.

I have previously said that we know very little of the chemical nature of the poisons we have been discussing. There are three theories which have been discussed in regard to these: (1) as to whether the poisons are albuminous substances; (2) whether they are of a ferment nature; and (3) whether they are crystalline chemical substances or, at any rate, not proteid.

Poisons of proteid nature.—Some of these poisons are so closely associated with proteids as to be inseparable. There is, for example, no question whatever that the albumoses of gastric digestion are poisonous when injected into the veins of an animal, and so also are the albumoses formed by the bacillus of anthrax, and that the poisonous nature of these substances is somewhat, although not greatly, diminished by heat. The poisons, however, which have given the greatest difficulty in the discussion as to whether they are of a proteid or of a ferment nature are those of abrus and ricin and a snake-poison. Abrus seeds, for example, contain a globulin and an albumose, both of which are poisonous, and if the globulin be precipitated from its solution by heat its toxicity is lost, and if the albumose is heated to a temperature of 85° C. its toxicity is also completely lost. In this case it may with plausibility be argued that inasmuch as the toxicity of both the bodies is destroyed at nearly the same temperature it is not the proteid itself which is poisonous but something associated with the proteids—that is, some body of a ferment nature. The same difficulty exists with regard to the question of snake-poisoning. Generally speaking, in the venom of the viperine snakes there are two proteid bodies, a globulin and an albumose, both of which are poisonous, and each of which appears to have a distinct action—the globulin acting more particularly on the blood, the albumose acting more particularly on the nervous system (C. J. Martin). If the globulin be precipitated from its solution by heating it to its temperature of coagulation its activity is destroyed, but the toxic properties of the albumose are still intact. Cobra venom does not contain so much globulin as that of the viperine snakes, so that heating its solution to the temperature at which the globulin is coagulated does not greatly diminish the toxicity of the venom and the solution requires to be boiled for a short time before the poisonous action is destroyed. From these facts it certainly appears that the toxic action of snake venom is so closely associated with the proteid as to be inseparable from it and that there is something in the constitution of the proteid moleoule—whatever that may be—which confers this great poisonous property on the venom.

Poisons of a ferment nature.—Several considerations, however, prevent the conclusion that all these poisons, including the bacterial, are of a proteid nature. Diphtheria poison, for example, is practically as toxic as cobra venom or as the venom of the Australian black snake (Hoplocephalus curtus). As previously stated, Roux and Yersin obtained the product from the broth solution in such a form that it acted in imponderable doses. Since that time, by means of the precipitation by zinc salts, and the subsequent decomposition of the zinc salt with carbonic acid, Brieger and Cohn obtained a toxic product from diphtheria, causing all the characteristic symptoms, but not giving any proteid reactions, neither the xanthoproteic nor the biuret reaction. It may be considered therefore that the diphtheria poison is not necessarily associated with a proteid. It may be that this poison, together with the poison of tetanus and that which we have discussed as formed by the typhoid bacillus, is of a ferment nature. The arguments which may be used in this respect are: (1) that they act in infinitesimal doses; (2) that they may act slowly and produce death after many days by profoundly affecting the general nutrition; and (3) that they are sensitive to the action of heat in a way which no chemical poisons are known to be. If, of course, these poisons are of a ferment nature their physiological action is unlike that of any of the other known ferments. They are not digestive ferments in the ordinary sense of the word. I have performed several experiments to test the digestive action on ordinary proteids of the diphtheria and tetanus poisons and have never obtained the slightest indication of digestion. If they are considered as ferments they must be substances which have a peculiar affinity for certain tissues of the body on which they produce their special toxic effect. Thus, the diphtheria poison selects the peripheral nerves for one of its chief actions and in some cases the spinal cord. The tetanus toxin produces its most marked effect on the cells of the spinal cord. Abrus, ricin, and the poisons of the three bacilli we have examined produce a pronounced effect on the body temperature, besides which they have a marked action on the small intestine. They have no pronounced effect on the nervous system except perhaps in the cases of abrus and ricin, which appear to affect the respiratory centre in the medulla. In each case, therefore, the ferment—if ferment it be—must be essentially different; for although they may have a similarity in action, yet their differences are considerable, and especially is this so in considering the results of the toxic reaction of these poisons in the body—the most delicate test for the identification of these poisons. Thus, in the case of abrus and ricin the action of the poison is closely similar, ricin perhaps acting rather more vigorously than abrin, so that so far as their physiological action goes, if that alone were investigated, they might be considered as identical substances, but Ehrlich found that an animal which had been made immune to abrin was not immune to ricin, and *vice versâ*. Similarly the diphtheria antitoxin does not counteract the effects of the tetanus poison nor does the tetanus antitoxin protect

[2] Simon Flexner: The Pathology of Toxalbumin Intoxication. Baltimore, 1897.

Digitized by Google

against the diphtheria poison. The association of digestive products with these poisons is an interesting one. In snake venom and in abrus albumoses are present, and these are also formed by the micro-organisms which we have been discussing. The amount of digestion, however, which each individual bacterium produces varies considerably, being greatest with the bacillus of anthrax and least with the typhoid bacillus. These products of digestion are formed, either by the bacillus ingesting the proteid and discharging it as albumose, or the digestion occurs by means of a proteolytic ferment secreted by the bacillus in the body of an individual or animal suffering from the disease. It may be interesting to add the following table[3] of the comparative toxicity of these substances. The figures represent the number of grammes of body weight of a rabbit which will be killed by 1 gramme of dried poison.

Cobra venom	4,000,000	Pseudechis	800,000 to 2,000,000
Hoplocephalus curtus ...	4,000,000	Pelias berus	250,000
Diphtheria toxin	4,000,000	Anthrax albumoses	3,000
Ricin	1,500,000	Cholera albumoses	3,000

THE RELATION OF THE TYPHOID BACILLUS TO ENTERIC FEVER.

The relation of the typhoid bacillus to enteric fever has been much discussed and some confusion has been caused in the subject by work which was done some years ago with non-virulent or slightly virulent forms of the bacillus. It is constantly present in cases of typhoid fever in the intestinal lesions, in the spleen, the mesenteric glands, and sometimes in the blood. It is in not a few cases found in the urine. It is also found—though not constantly—in the fæces. The constant presence of this pathogenic organism in the lesions of the disease is one of the arguments in favour of its being the cause of the condition, and in most cases—as we have seen — it may be obtained in pure culture from the spleen after death. The second argument in favour of the bacillus being the cause of enteric fever rests on the sedimenting reaction and Widal's reaction which is given by the blood-serum of typhoid patients in certain dilutions, causing the bacilli from a young culture to become motionless and to clump together and sink to the bottom of the vessel in which they are contained. This reaction is specific; it is not given by the bacillus coli, but according to Dr. H. E. Durham it is given to some extent by the bacillus of Gärtner. A similar reaction was obtained from the blood-serum of animals which have been rendered artificially immune to the typhoid bacillus. We must consider, therefore, that the serum reaction given by typhoid patients is due to the effects of the typhoid bacillus which is present in their bodies. It is a noteworthy fact, that normal rabbit serum gives a clumping reaction with the bacillus coli and that the serum reaction with the bacillus coli, when artificially prepared coli serum is used is, according to Dr. Durham, very variable. Typhoid serum never gives a reaction with the bacillus coli, nor does the bacillus coli serum give a reaction with the typhoid bacillus. This constitutes an important difference between the micro-organisms. The difficulty with regard to the question of the typhoid bacillus rests mainly (1) on the fact that this disease does not exist in the natural condition in any animal but man. In man it is a very characteristic disease with definite intestinal lesions and a definite enlargement of the mesenteric lymphatic glands and of the spleen. (2) Another statement which has been made is that the typhoid bacillus is not infective. With regard to the first point, enteric fever is in the same position as any of the other diseases which affect man alone, and the difficulty is removed if it can be shown that the typhoid bacillus reproduces the same lesions as occur in the human being. Many attempts have been made to infect animals by way of the alimentary canal with the typhoid bacillus and most of them have been unsuccessful. The want of success does not appear to depend solely on the fact that non-virulent bacilli have been used, but also on the fact that the animals are extremely insusceptible to infection through the alimentary tract by the typhoid bacillus. In my experiments I gave two rabbits enormous and daily doses of the virulent bacillus with the production of no result beyond fever in one animal lasting a day. Remlinger[4] appears to have been more successful and to have produced in some rabbits a definite infection by giving them virulent cultures in their food. Some rabbits were unaffected and others, after a period of fever, diarrhœa, and bodily depression with loss of weight, underwent complete recovery; others again were affected in the same way and succumbed. At the post-mortem examination there was great congestion of the small intestine which contained liquid matter. Peyer's patches were enlarged and there was some ulceration at the level of the cæcum. The spleen was greatly enlarged and the bacillus was obtained in a pure culture from the organs. In one experiment the animal was fed for 5 days with the typhoid bacillus; on the eighth day fever was observed and there was the train of symptoms which had been mentioned up to 17 days, when the animal was dying. In another experiment, 7 days after feeding the fever began and the symptoms progressed for 20 days, when the animal died. Similar results were obtained in rats. One important point is noted by Remlinger—viz., that the blood-serum of the animal infected gave an agglutinating or sedimenting reaction. There can be no question from these experiments that an infection of the animal by way of the alimentary tract was produced, and that the chief stress of the disease was on the small intestine. It may be remembered that a similar difficulty in infecting animals with the cholera vibrio by way of the alimentary tract exists, although this can be effected if the acid contents of the stomach be first neutralised with alkali, as was done by Koch. A true infection follows the injection of the virulent bacillus into the peritoneal cavity or into the venous system, and also under the skin, although to a lesser extent; that is, there is a dissemination of the bacilli through the organs of the body and the blood. In some animals, however, it may be absent in the blood, and this was found also by Remlinger in his cases of intestinal infection. An interesting point in the infection of the animal body by the typhoid bacillus is that although the non-virulent forms of the bacillus are not toxic they may become so and may infect the body when products of certain other micro-organisms are injected at the same time. I have previously mentioned these experiments, and the chief point which is noteworthy is that the injection of the products of the bacillus coli into the peritoneal cavity at the same time as the injection of the living typhoid bacillus under the skin aids the distribution of the bacillus throughout the body. At death in such cases it is found in the peritoneal cavity and in the organs of the body. This does not occur if the non-virulent typhoid bacillus is injected by itself. The products of other micro-organisms will also do this. In some cases enteric fever appears to be a pure infection of the typhoid bacillus; in other cases it is a mixed infection, or there may be infection after the acute disease is over, usually by pus organisms. It has been found in some cases in the course of typhoid fever that the bacillus coli, which is naturally found there, becomes more virulent than it is in life and increases greatly in number. It is possible therefore that these two organisms react on each other, one aiding infection by the other. It is known that the products of the bacillus coli aid infection by the typhoid bacillus, and cases in which there is infection by the bacillus coli during the course of typhoid fever have been observed, for example, in abdominal abscesses and cystitis.

It has been much discussed whether enteric fever is a primary intestinal infection or whether it is a general infection with an intestinal lesion—that is, whether the bacillus primarily infects the Peyer's patches and from there is distributed to the mesenteric glands and the spleen, or whether the micro-organism is introduced into the body in some other way unknown and infects the body, producing an enlargement of the spleen and ulceration of the Peyer's patches in the intestine as part of the general infection. The arguments which have been used for considering enteric fever a general infection with a secondary intestinal lesion are not very satisfactory. It has been said that inasmuch as the bacillus is not constantly found in the motions and is constantly found in the urine it would appear that there are not many bacilli in the intestine such as would exist if the intestine were primarily affected. There is nothing whatever in this argument, inasmuch as even if there were a primary intestinal infection we can readily see that the bacilli might not be discharged in the fæces in sufficient

[3] See C. J. Martin: Physiological Action of Venom of Australian Black Snake, Royal Society of New South Wales, 1895. Martin gives the toxic value of the anthrax albumoses as 80, quoting my earlier work. My later experiments give the toxic value as 3000. See also Calmette, Annales de l'Institut Pasteur, vol. viii., 1894.

numbers to be readily found. Moreover, if there is a great increase in the number of bacillus coli in the intestinal tract, not only is there great difficulty in finding the typhoid bacillus in the presence of large numbers of this micro-organism, but the more vigorous bacillus coli might actually beat out of the field the less vigorous typhoid bacillus. As regards the passage of the typhoid bacillus in the urine this would as readily occur from an intestinal infection which is followed by a general infection as when there was a general infection primarily.

Another argument which has been used, and which is perhaps somewhat stronger than the first, is the result of Sanarelli's experiments. He found that, however introduced into the body—whether through the venous system, or subcutaneously, or into the peritoneal cavity—the stress of the disease produced by the typhoid bacillus and its poison was on the abdominal organs and chiefly the intestines, which showed what he described as "acute mucous inflammation." The Peyer's patches were described also as swollen. From these results Sanarelli was inclined to look upon the infection as a general one with a local intestinal lesion, but the results obtained by him are not due to an infection of the body by the bacillus, but to the action of the poison of the bacillus. Moreover, the effect on the intestine is due to the poison and not to the infection. It is not due to the fact that the bacilli introduced under the skin or into the vein, so to speak, get buried in the mucous membrane, where they produce a lesion, but it is due to the selective action of the poison on the small intestine—a selective action which, as we have seen, is not limited to the typhoid poison, but is also possessed by the poison of Gärtner's bacillus and of the bacillus coli and also by the two vegetable poisons, abrus and ricin. The result of producing an intestinal lesion by the subcutaneous or intravenous injection of a poison is not limited, therefore, to the typhoid bacillus, and the question is really one not of the action of the bacillus itself, but of the action of the poison introduced with it. It has been a question in these intestinal lesions whether ulceration can be produced by the intravenous injection of a poison. Ehrlich stated that ulceration sometimes followed poisoning with ricin and abrus. In my own experiments such ulceration was never observed, and it was not observed by Flexner. From what we know of other intestinal infections the view that the infection in enteric fever is primarily intestinal is the more logical. The part of the intestine infected—viz., the Peyer's patches—is the least protected part of the mucous membrane, and is a tissue of only slight metabolic activity covered with a single layer of epithelium with no villi, whereas the rest of the mucous membrane is covered with villi which are more or less constantly in a state of active metabolism. Moreover, in tuberculosis produced by feeding the Peyer's patches of the intestine are the first infected, and I cannot conceive of any general intestinal ulceration occurring in the absence of a local infection. In tuberculosis ulceration of the intestine never occurs as the result of general infection, and the ulcerations of the upper part of the small intestine which sometimes occur in septicæmia and pyæmia are always few in number (one or two) and are irregular in situation.

In conclusion, I wish to express to you, Sir, and to the College my sense of the great honour you have conferred upon me by appointing me to deliver these Croonian Lectures and I gladly acknowledge the great help I have received from my two assistants in the investigation—Dr. Greig, my assistant in bacteriology at University College, and Dr. R. Row, of Bombay. Both these gentlemen by their devotion and skill have contributed greatly to whatever success has attended the investigation.

HEALTH OF SOUTH DEVON.—Mr. W. Harvey has just presented to the Devon County Council his annual report on the health of South Devon. The general death-rate during 1897 was 14·1 per 1000, only 0·1 higher than the lowest rate recorded; the birth-rate was 23·5, the lowest ever recorded. Only 6 of the 24 urban districts have an isolation hospital and Torquay alone has made provision for disinfection, although Paignton and Teignmouth have taken action in the matter. All the towns make use of the Dairies Order, 1885, but Torquay, St. Thomas, Kingsbridge, Cockington, Buckfastleigh and Brixham have not adopted the Infectious Diseases Prevention Act, 1890.

NOTES OF A SERIES OF CASES OF ABDOMINAL SURGERY.[1]

BY E. T. DAVIES, M.D., F.R.C.S. EDIN., M.R.C.S. ENG.,
LATE SENIOR ASSISTANT SURGEON TO THE HOSPITAL FOR WOMEN, LIVERPOOL; SURGEON TO THE LIVERPOOL SAMARITAN FREE HOSPITAL FOR WOMEN.

THE following cases illustrate very well the eminent tolerance of the peritoneum to surgical interference. Not so long ago all serous and synovial membranes were regarded as territories which should never be entered or explored by the surgeon except under the most imperative circumstances. Now, happily, these groundless fears are dispelled and these cavities are explored and manipulated by the surgeon, one might almost say, with impunity, always recognising, of course, the paramount importance of using the most rigid antiseptic precautions.

CASE 1. *Rupture of a ventral hernia with protrusion of the greater portion of the small intestines for over twenty-four hours; bowels washed and returned; recovery.*—This is a remarkable case and, so far as I know, is unique. The patient was a married woman, aged twenty-nine years, of dissolute habits, the mother of two children. Some months after the birth of her last child she was admitted under my care to the Hospital for Women suffering from a pelvic abscess which was pointing in the middle line above the pubes. This was incised through the linea alba, much pus was evacuated, and the abscess cavity was flushed and drained. She made an uneventful recovery and was discharged cured and enjoined to wear an abdominal support. In about a year afterwards her husband called at my house late one night wishing me to visit his wife in a slum street, stating that she had "burst." Not interpreting the man's statement in its literal sense I did not go that night but went in the afternoon of the next day, when I found the woman lying on the floor in the corner of a common living room amongst a heap of straw and filthy rags. On questioning her she made the same reply as her husband had on the previous night—namely, that she had "burst." She was lying in the semi-prone position, facing me, and on turning down the scant apparel which covered her I was at once confronted by a ghastly heap of small intestines in front of her amongst the straw and dirt. She told me that in the afternoon of the previous day whilst stooping over the fire stirring some porridge she suddenly felt her abdominal wall give way at the site of the former incision and her bowels shot out. It will thus be observed that the major part of her small intestines had been protruded and exposed to every abomination for a period of twenty-four hours. With the assistance of a medical friend and a nurse I promptly proceeded to return this mass of bowels into the abdominal cavity. For light we had to send out for a halfpenny tallow candle. Our operating table consisted of an old soap box with the patient's head over-hanging one end and the lower extremities the other. My friend administered chloroform whilst I with the assistance of the nurse proceeded to wash and cleanse the protruded intestines with plain unsterilised water drawn from the tap hard by in a not over clean basin. The opening of the parietes had to be enlarged above and below and with some difficulty we succeeded in returning the intestines into the abdominal cavity; a glass drainage-tube was inserted at the lower angle of the wound, sutures were applied, and the patient was removed to her bed of straw on the floor as quickly as possible. I need scarcely say that we entertained no hope of even a rally from the shock of the operation, to say nothing of her ultimate recovery. Any way, on my calling on the following morning to my great astonishment she appeared to be remarkably well in all respects. She had passed a comfortable night without pain or vomiting. The dressings were changed and the drainage-tube was withdrawn. Suffice it to say that she made a rapid and uninterrupted recovery and remained well and free from recurrence of hernia for some years afterwards. I learnt lately, however, that she finally succumbed to pulmonary phthisis, induced perhaps by her profligate habit of living.

CASE 2. *Twisted pedicle; rupture of cyst; diffuse peritonitis; collapse; ovariotomy; recovery.*—The patient was a large-framed, fat, and flabby woman, a widow, aged forty-nine years. She had had ten children and three miscarriages. The menopause had taken place one year previously. When she was admitted into the Hospital for Women, on March 19th, 1896, she was in a most alarming condition. Her previous history was something as follows. Two days before her admission, whilst at stool, she was suddenly seized with violent pains in her abdomen and back, cramps, vomiting, and retching. She took a Seidlitz powder, which moved the bowels but slightly, afterwards no fæces or flatus being passed for several days. The district nurse was summoned in the first instance and she, finding the patient so extremely ill, called in the nearest medical man, who in turn advised her instant removal to the Hospital for Women. When she came under my observation two days after the onset of her illness her abdomen was greatly distended and intensely painful; she had bilious vomiting and complete blockage of the bowels both as regards flatus and fæces; in fact, she had the usual signs of acute diffuse peritonitis. It was apparent that something had given way in the abdomen and the most likely thing was a twisted ovarian pedicle or a ruptured ovarian cyst or maybe a combination of both. Under these circumstances a consultation with my colleagues was hurriedly called with the view of opening the abdomen without delay. They, however, considered the patient to be in such an extremely critical condition—too critical to withstand the shock of an abdominal section—that they advised delay in operating with the hope of her rallying somewhat. This course was therefore adopted and during the next few days her condition varied considerably. The treatment was conducted on the usual stereotyped lines—namely, opiates, stimulants, poultices, turpentine enemata, &c. By-and-by we succeeded in getting a slight action of the bowels, a little flatus passing but no fæces, the other symptoms remaining pretty much the same. Suddenly one morning the patient took a decided turn for the worse. She became collapsed, her skin was cold and bedewed with clammy sweat, she was almost pulseless, and her voice was a mere whisper. I happened to see her shortly afterwards and to all appearance she seemed to be sinking fast. It seemed a pity to let the woman drift to her inevitable death without giving her the only chance of saving her life, so I felt impelled to open the abdomen, clear up the diagnosis, and do what I could for her surgically. She was carried into the operating theatre on a stretcher and, with the assistance of a colleague, I performed abdominal section as quickly as possible. On reaching the peritoneal cavity the first object which presented itself in the line of incision was a greenish, sloughy-looking structure, which proved to be a ruptured ovarian cyst with its pedicle twisted. Soft adhesions had formed between the cyst and parietes in every direction. The tumour was speedily freed from its connexions, the pedicle was transfixed, tied in two parts and the cyst was cut off. Both the parietal and visceral peritoneum were deeply injected and there was evidence of acute diffuse peritonitis. The abdominal cavity was quickly flushed with plain warm water drawn from the tap—there being no time for sterilising—and a drainage-tube was passed into the pelvis at the lower angle of the incision. The incision was quickly closed with silkworm gut sutures and the patient put to bed, kept warm with hot-water bottles and stimulated by hot water and brandy enemata. The patient rallied from shock in a wonderful manner and her recovery was rapid and complete. In the course of a few weeks she was discharged from hospital wearing an abdominal support. On account of the extreme laxity and fatness of this woman's parietes and also having to work very hard for her living she presented herself again at the end of a year, but this time with a large ventral hernia at the site of the former incision. I admitted her into hospital and operated again on the hernia with complete success She still wears an abdominal support. I have come to the conclusion that in desperate cases like the foregoing speed in operating is a great element of success.

CASE 3. *Tuberculous kidney; nephrectomy; fæcal fistula through the loin; recovery.* — The patient was a woman aged twenty-nine years. She had been married seven years and had had three children, the last being born eight months ago. The onset of the present illness took place two years ago when, shortly after the birth of her second child, she complained of pain in the back and subsequently she noticed a lump in the left side of her abdomen which became painful. She did not seek medical advice for it and in a while she became pregnant of her third child. Her bladder became unduly irritable but she took no notice of the character of the urine. In due course she was confined and her medical attendant says that she had an easy and natural labour. After the birth of the child her medical attendant also discovered a swelling in the left half of her abdomen and suspecting it might have some connexion with the left kidney he examined the urine and found it contained pus and albumin. After several months of waiting she was sent under my care at the Hospital for Women. At this time she was extremely emaciated, had profuse night sweats, a jumpy temperature, and a large amount of pus in the urine, but no blood at any time. The left half of her abdomen was occupied by a large, prominent, fluctuating swelling extending from the costal arch to the iliac fossa and extending backwards in the loin towards the spine. The diagnosis made was a cystic enlargement of the left kidney, most probably of a tuberculous nature. The absence of blood and renal colic contra-indicated to some extent both stone and cancer. Her family history was perfectly satisfactory, there being no tendency to tubercle in any member of her family. After consultation with my colleagues an exploratory operation was decided upon and this I did by the transperitoneal rather than by the lumbar route, and for two reasons: firstly, because it was absolutely necessary to ascertain in the first instance the exact condition of the right kidney; and secondly, because of the large size of the tumour. An incision was accordingly made through the left semilunar line extending from the costal arch to below the iliac crest, and after the peritoneal cavity was entered the hand was passed into the right loin and the kidney was carefully examined and found to be apparently sound. The peritoneum on the outer aspect of the descending colon was next incised and the kidney-capsule was found to be greatly thickened and firmly adherent to the surrounding structures—above to the dome of the diaphragm, behind to the loin, and in front to the posterior aspect of the colon. So firmly fixed, indeed, was it that we experienced considerable difficulty in turning the tumour out of its bed. The tumour was next freely incised and about 2 pints of curdy pus were evacuated; the pedicle was sought, the renal vessels and the ureter were tied separately, and the mass was cut away. The seat of operation being thoroughly cleansed with warm water a counter opening was made through the structures of the loin, a rubber drainage-tube was inserted, the colon was laid back in its place, the abdominal incision was closed completely, and the patient returned to bed. She bore the operation very well and made an uneventful recovery without a hitch in so far as the kidney was concerned, the remaining kidney performing its double function in a perfectly satisfactory manner. I have to say here, however, that an unfortunate circumstance cropped up and it is this. In drawing the descending colon inwards towards the median line from off the face of the kidney tumour, which I have just said was firmly adherent to the capsule, the posterior wall of the colon must have been damaged, for in the course of a week or so after the operation fæcal matter began to make its appearance through the rubber drainage tube in the loin and hence it became obvious that a fæcal fistula had formed. The amount of discharge lessened and in due time the drainage-tube was withdrawn and I was sanguine that the fistula would spontaneously close, but up to date there is still a small leakage of fæcal matter and sometimes flatus through a small fistulous opening in the loin, otherwise the patient is very well.

CASE 4. *Impacted gall-stones; intense jaundice; cholecystotomy; recovery.*—The patient was a married woman, aged forty-two years, with fat and flabby tissues, the mother of seven children, the last nine months old and still on the breast. For some years she had been subject to what she called "bilious attacks," which seized her at irregular times in the form of spasmodic, crampy pains in the abdomen, with retching and vomiting. The patient said that one of these bouts, some two or three years ago, was worse than the rest and was followed by jaundice which soon passed away. She did not seek medical advice for it. The present attack seized her in the early part of last October and was much more severe than any of the previous ones. She had violent colicky pains in the epigastrium which shot through to the back of the shoulders and particularly to

Digitized by Google

the right shoulder tip, retching, vomiting, jaundice, portery urine, clayey stools, recurrent rigors and fluctuating temperature ranging from 101° to 103° F. She came under my observation four days after onset of illness and I found matters as just described. The physical signs were not conclusive of the existence of gall-stones, but one could not examine her very thoroughly because of the exacerbation of pain which it excited. There was, however, an undefinable sense of resistance to be made out in the region of the gall-bladder and the subjective symptoms were so markedly characteristic of gall-stones that I had no hesitation in making a diagnosis of impaction. She was treated for a fortnight on general principles and with the usual negative results. It soon became obvious that the patient was drifting—she was emaciating rapidly, the jaundice was deepening, and there were recurrent rigors with high temperature, &c. Under these circumstances I determined to explore the gall-bladder and this I did with the assistance of some medical friends and under conditions which were certainly not of the most favourable and sanitary kind. A vertical 3 in. incision was made from the tip of the ninth rib in the right semilunar line. On opening the peritoneum two fingers were passed in and the gall-bladder was found contracted and retracted beneath the liver border, so much so that we experienced some difficulty in bringing the viscus into view in the parietal wound. The area of operation having been packed with sponges to prevent soiling of the general peritoneal cavity, the fundus of the gall-bladder was seized with a pair of pressure forceps in order to bring it to the surface, but its walls were so soft and friable that they at once crumbled to pieces in the jaws of the forceps. With some difficulty we succeeded in bringing the gall-bladder into the parietal wound and the tear just made in its fundus was enlarged with scissors. Some mucoid prune-juice-coloured stuff was evacuated, the finger was passed in and four black-coloured stones were readily brought away. I felt convinced that there must be another stone, or stones, impacted further away in the track of the other biliary ducts—hepatic or common—which would explain the urgency of the symptoms. With this view the biliary ducts were explored with fingers and probe both by myself and by Dr. Smart, who assisted me, but with a negative result. The parts around the site of operation were so matted together by adhesive inflammation that the exploration of the biliary passages could not be effected so thoroughly as we would have wished. The sponges were now withdrawn, the field of operation was well flushed with warm water, a gauze drain was passed into the peritoneal cavity below the liver surface, a rubber drainage-tube was placed within the gall-bladder and its incised walls were sewed to the parietal wound, excluding the skin. Several layers of absorbent dressings were applied over all and the patient was returned to bed. She rallied well and next day the dressings were changed and the gauze packing was removed. For some days there was a copious flow of bile through the drainage-tube, afterwards it materially lessened, and at the end of a week the rubber drain was also removed and we had now a biliary fistula established. The flow of bile through the fistula varied very much from day to day, and usually flowed in gushes. The case ran an uneventful course after the operation. All the urgent symptoms quickly subsided. There were no more rigors, the temperature descended to normal, and the amount of bile passing by the kidneys markedly diminished; but the stools bore a clayey appearance for some time, the jaundice disappeared slowly but steadily, and she was soon convalescent. The gall-bladder was frequently injected with various reputed gall-stone solvents—e.g., olive oil, turpentine, ether, and plain water, but with no appreciable benefit. It was interesting to notice the exit of some black débris on several occasions through the fistula. More than once these fragments blocked the fistulous track, which I scooped out with a grooved director. By-and-by the discharge of bile by the fistula ceased and began to appear in the stools. My own view is that, with the subsidence of surrounding inflammation and removal of bile-tension, the calculi and débris impacted in the biliary ducts became dislodged, disintegrated, and passed on by the duodenum or by the biliary fistula. Be this as it may, the patient is now in the enjoyment of perfect health without a vestige of her former ailment. In this case we had to conduct our procedure under very adverse surroundings—a poor artisan's stuffy dwelling in a slum street with no trained nurse, &c.

Liverpool.

HÆMATURIA AS A SYMPTOM: METHODS EMPLOYED IN MAKING A DIFFERENTIAL DIAGNOSIS;

WITH 19 CASES ILLUSTRATING POINTS OF INTEREST IN THE DIAGNOSIS OF RENAL AFFECTIONS CHARACTERISED BY THE PRESENCE OF BLOOD IN THE URINE.

BY DAVID NEWMAN, M.D. GLASG.,
SURGEON TO THE ROYAL INFIRMARY, GLASGOW.

(Continued from p. 18.)

Catheterisation of the Ureters.

THIS method of examination is not so necessary in cases of hæmaturia, nor is it so reliable as in those of pyuria; not necessary because generally if the hæmaturia is purely renal the escape of blood from the ureter can be readily seen by means of the cystoscope, and not reliable because the use of the catheter may cause hæmorrhage. To perform such a delicate operation by the sensation of touch alone is very difficult and it is only by patient and prolonged practice on dead subjects that one can hope to succeed in performing the operation on the living, but once the art has been mastered it is easier to pass a catheter into the living ureter than into the dead one.

Catheterisation of the ureter in the female has been much simplified by Kelly of Baltimore.[1] The essential feature of his method is that of the introduction of a straight speculum into the empty bladder. The walls of the viscus are slightly separated by the position assumed by the patient, the dilatation being such as to bring the orifices of the ureters into view, when reflected light is thrown into the bladder by a forehead mirror. I have repeatedly used this method and found it simple and satisfactory, and easier of application than the method I first employed, which required very considerable practice and dexterity. Those who desire to catheterise the ureters must carefully study their direction in the various parts of their course and must always remember that gentle manipulation is of the highest importance. I have frequently succeeded in carrying out catheterisation of the male ureters by the special catheters devised for the purpose without the aid of any light.[2]

Within the last few years two catheterising cystoscopes have been introduced, the one by Nitze and the other by Casper. The former instrument I have not had an opportunity of using, but the latter I have employed in a number of cases and find it a considerable improvement upon my own method, and I have no doubt other surgeons also will find it a very valuable instrument when they have become accustomed to manipulate it. Some surgeons, however, who do not take the trouble to gain the necessary dexterity in the use of such instruments are apt to condemn them or to entrust them to experts only, but the use of the cystoscope and the catheterising cystoscope will, I have not the least doubt, become more general, just as the ophthalmoscope, laryngoscope, and rhinoscope have ultimately asserted their position as aids in diagnosis. In catheterising the ureters it must be borne in mind that rough introduction of the catheter may of itself lead to hæmorrhage and certainly this is a drawback to its use, especially when the catheterised ureter is the seat of inflammation. In the female the procedure is easily carried out and the results are tolerably certain, but in the male even when one succeeds in introducing the catheter into the ureter it is difficult to say to what degree the results obtained are to be relied upon.

A point of considerable importance in diagnosis is the appearance of the orifice of the ureter as seen by the cystoscope. This question I cannot discuss in detail at present, but it may be stated as a general observation that when there is distinct evidence of irritation at the orifice of one ureter while the other is normal in appearance it may be safely inferred that the lesion producing the hæmaturia is on the side of the morbid ureter.

3.—By estimating the Quantity of Hæmoglobin and comparing it with the Amount of Albumin in the Urine.

Urine containing blood is always albuminous, but the relative proportion existing between the red corpuscles and the serum depends upon whether or not the hæmorrhage is associated with inflammation. For example, in acute nephritis the general inflammatory hyperæmia causes large quantities of albumin to pass into the urine independently of the hæmorrhage. The relationship between the quantity of hæmoglobin and the amount of albumin in the urine will therefore aid one in determining the seat of the hæmorrhage. In 1880 I showed at a meeting of the Glasgow Pathological and Clinical Society an apparatus for estimating by a simple method the quantity of hæmoglobin in solution. The quantity of hæmoglobin having been estimated and the amount of albumin determined by one or other of the recognised processes the two results should be compared. If the ratio of albumin to hæmoglobin is as 1 to 1·6, then it may be concluded that the appearance of albumin is entirely due to the presence of blood; but if the quantity of albumin is much increased beyond the proportion just mentioned the indication is in favour not only of an independent albuminuria, but also of a renal affection as the cause of the hæmaturia.

4.—By carefully considering all the other Objective and Subjective Phenomena.

The questions which have been considered up to the present give but a rough sketch, the detail requires to be carefully filled in before the picture is completed. In order to do this the practitioner must consider the most common sources of hæmaturia and enumerate the various lesions of the kidneys, the ureters, the bladder, the prostate, the urethra, and the testicles which may give rise to the symptom under discussion. It is well always to conform to this rule in going over the etiological factors which have been indicated above.

Before illustrating or discussing in detail these individual lesions it may be well to make some general remarks as to the characters of the urine in renal hæmaturia, and it may be here stated that the cases are brought forward only to illustrate the etiology and symptomatology of hæmaturia, the question of treatment not being discussed in the present paper. Placing aside for the present the hæmaturia due to hydatid disease, the renal hæmorrhages of the greatest practical importance from the standpoint of this paper are those arising from injury, renal calculus, tumours of the kidney, and tuberculous disease of that organ. Having determined that the hæmorrhage is not from the lower urinary tract it remains to ascertain which of those four causes is to blame.

When the hæmorrhage is due to renal calculus it is usually small in amount, sometimes constantly present but generally with more or less prolonged intervals and commonly oft-repeated. In some instances, however, the hæmaturia is very slight, while in other cases it may be the only symptom. The bleeding is not closely related to pain or to the development of other symptoms, but as a rule it is increased by movements of the body. This, however, does not always follow immediately, but a short interval may elapse—hours or even days—between the exertion and the appearance of the blood in the urine. While the hæmaturia of renal calculus is more copious after exercise, rest in bed usually appreciably diminishes it. This peculiarity is most characteristic. The blood, it must be borne in mind, is derived from the renal pelvis and not from the parenchyma; consequently renal blood-casts are not found in the urine and the quantity of albumin is fully explained by the presence of blood. When the urine is evacuated the blood is thoroughly mixed with it, but not so intimately as when the cause of the hæmaturia is structural disease of the kidney, and if the urine be allowed to stand for a few hours the blood corpuscles are readily precipitated and leave the supernatant urine clear. If free from blood the urine will also be found to be non-albuminous. The presence or absence of pus in the urine will be determined by the circumstance whether or not the calculus has induced inflammatory changes, and the existence of a swelling in the renal region will depend upon the amount of freedom for the escape of urine by the ureter. Renal hæmorrhage from tumour is generally more profuse and less transient than from calculus, and in not a few cases it is so copious as to cause marked anæmia—a result seldom induced by calculous hæmaturia. It is often developed without any preceding pain. In calculous disease injury or exercise commonly provokes the bleeding and therefore one finds the hæmorrhage more profuse during the day while the patient is moving about. The bleeding from tumours is, on the contrary, most likely to occur during the night, while the patient is at rest in the recumbent posture. The urinary deposit may assist one in the diagnosis. Concretions composed of oxalate of lime, uric acid, phosphates, or urates, may indicate the character of the stone, while by carefully filtering the urine in cases of tumour portions of the growth may be procured for microscopic examination. The presence of a persistent swelling in the renal region associated with considerable hæmaturia is of significance and may be held as clearly indicating the presence of a neoplasm in the kidney. Exceptions to this rule have, however, been recorded by Ebstein, Hirtz, and Fleming. But while this is so it must not be forgotten that the presence of a palpable new formation may for a considerable time be preceded by the presence of blood in the urine. Considerable distension of the pelvis may be produced by a calculus obstructing the ureter and so lead to a swelling in the renal region, or the bulging in the loin may be caused by enlargement of the kidney from tuberculous disease; in neither of those conditions, however, does hæmaturia frequently occur. In the latter the very obstruction which causes an increase in bulk of the kidney prevents the hæmorrhage.

Although much difficulty is often experienced in distinguishing calculous hæmaturia from that caused by tumours there is still greater care required in the diagnosis between the hæmorrhage of early tuberculous disease and that of renal calculus. The symptoms of the two latter conditions are sometimes identical. This is especially so when the patient fails to show any other evidence of tuberculous disease than that revealed by the renal lesion. In tuberculous disease hæmaturia is frequently absent for long intervals, is seldom so severe as in stone, and is not increased by exercise. In both conditions pus may be mixed with the urine, but while in the latter concretions and gravel may be discovered, in the former careful and repeated search may demonstrate the presence of tuberculous bacilli. In the early stage of tuberculous disease of the kidney the quantity of albumin in the urine is generally in excess of that accounted for by the blood and in the later stages when pus appears in considerable quantity, the pus and blood are not so rapidly or so completely precipitated from the urine as in calculous pyelitis. The presence of phthisis pulmonalis, tuberculous disease of bones or joints, of the testicle, the prostate, the vesiculæ seminales, the mesenteric glands, the intestine, or of the lower urinary tract, may give a clue to the cause of the hæmaturia. I will now endeavour to describe more in detail, and illustrate by cases, the various lesions of the kidney which are associated with more or less profuse and persistent hæmaturia.

1.—Traumatic lesions.

(a) From injury.—In hæmaturia consequent upon injury of the kidney the urine is generally scanty and highly coloured with blood, and long thin coagula, casts of the ureters, may be observed. The presence of blood in the urine in such cases does not necessarily denote rupture or laceration of the organ; and, on the other hand, severe injury may be sustained by the kidney without blood at any time appearing in the urine. The latter contingency may arise either as a result of plugging of the ureter by a clot, or as a consequence of rupture of the ureter from the violence which caused the injury to the kidney, or in rare instances it may be due to the rupture of the kidney being so extensive that the blood escapes into the perinephric tissue only and not through the ureter to the bladder.

CASE 2. *Transverse rupture of the right kidney with a great effusion of blood behind the peritoneum and into its cavity; death from peritonitis on the fifth day.*[3]—The patient, a man whom I saw in private, fell from a height of 36 ft., alighting first upon his right foot and thence on the buttock; he dislocated his right hip-joint and ruptured the kidney on the same side. The patient was seen within a few hours of the accident and then to the naked eye there was no appearance of blood in the urine, but within six hours a long, narrow clot, probably a cast of the ureter, was

[3] Royal Infirmary (Glasgow) Museum, Series vii., No. 14.

Digitized by Google

evacuated along with a quantity of deeply blood-stained urine. On the following day there was a distinct fulness in the flank corresponding to the position of the right kidney and the hæmaturia continued, but no more blood-clot was observed. The patient complained of a dull, aching pain in the renal region; this was increased greatly by deep inspiration or movement of the body, and on palpation there was great tenderness. The patient died from peritonitis on the fifth day, and at the post-mortem inspection a considerable quantity of blood was found effused behind the peritoneum and into its cavity, and the cortex of the kidney was ruptured transversely in many places, but not to any great depth.

In some individuals very slight concussion may cause hæmaturia independently of the existence of renal calculus, and in those instances recovery usually takes place within a short time. Sprains of the lumbar region may cause the appearance of blood in the urine. The hæmorrhage in such cases is easily explained. When the spine is acutely bent upon itself, as it was in the case just mentioned, the kidneys, being firmly bound to the column, are made to describe a contortion similar to that of the spine, as a consequence of which not only may the convex aspect of the organ be lacerated and torn transversely, but the sudden jerk may force the kidney away from the middle line and tear the pelvis or the ureter. The blood may therefore escape in two ways—into the tissues surrounding the kidney, where, if the patient survives, it may give rise to perinephric inflammation and abscess, or by passing down the ureter it may give evidence of the injury the kidneys have sustained. But while laceration of the kidney may occur without a bruise in the loin, in the majority of instances a blow upon the lumbar region is the direct cause.

There is not much difficulty in diagnosing this form of hæmaturia. The history of a lumbar sprain or of a blow or crush on the loin, indicated perhaps by ecchymosis, leads one to suspect rupture or contusion of the kidney. Severe damage to the kidney may, however, exist independently of any injury to the other abdominal organs and may of itself prove rapidly fatal; but in the great majority of cases there is evidence of violence elsewhere, and there are symptoms of rupture of other internal organs, especially of the spleen and liver. Generally, there will be marked and rapid collapse, pain in the course of the ureters as well as in the lumbar region, retraction of the testicle, difficulty in micturition, or even anuria. The following case is an instructive one and may be quoted as showing how one might be led astray—it is detailed in "Surgical Diseases of the Kidney."[4]

CASE 3. *History of a fall followed by ecchymosis in the left lumbar region; hæmaturia, suspected at first to be due to laceration of the kidney but latterly demonstrated to be from a papilloma in the bladder.*—"Three years ago an instructive case came under my notice in private practice. A boy aged fifteen years fell a distance of 12 ft. and alighted on his side, which struck violently against the edge of a packing-box. When I saw him he was unconscious, and the only facts I could arrive at were the history of a fall, the circumstance that there was ecchymosis over the right eye and in the left lumbar region, half-way between the lowest rib and the crest of the ilium, and the presence of blood in the urine. The lad remained unconscious for two hours, but with the exception of severe pain in the head for a few days he had no bad symptoms. The hæmaturia continued, however, and on more minute inquiry I found that the urine had previously to the accident 'been red when passed,' and when the patient had recovered from the injury due to the fall I discovered for the first time that he had a small papilloma in his bladder from which blood continued to flow at irregular intervals. In this case, from my inability to obtain information respecting his past history, I at first believed the hæmorrhage to be from the kidney, which I thought had been injured by the fall, but subsequent investigation showed that in this assumption I was entirely wrong. It will therefore be seen that while hæmaturia is one of the most reliable symptoms of contusion or laceration of the kidney from traumatic causes cases of injury in the lumbar region may coexist with hæmorrhage without these circumstances being related to one another as cause and effect."

In cases where the kidney is bruised without laceration of its tissues hæmaturia may be present for a few days after the accident. The bleeding is not usually prolonged or severe and the appearance of blood in the urine may not closely follow upon the injury; its appearance, indeed, in some cases may be delayed for hours, or even for days, through a blocking of the ureter by a coagulum. The following case illustrates this:—

CASE 4. *History of a fall with bruising; severe pain and swelling in the left lumbar region, followed three days afterwards by a copious hæmaturia, coincident with relief of pain and disappearance of swelling in the loin.*—A man, aged sixty-four years, was admitted to the Glasgow Royal Infirmary on April 1st, 1896, and he stated that a fortnight previously to admission he had fallen a distance of 30 ft. and landed, he thought, on his buttock, but on recovering from the immediate shock of the injury he suffered from a severe lacerating pain in the left lumbar region. The following morning he had so far recovered that he resumed his work, even although the pain in the region of the kidney was very severe. In the evening of the second day after the accident he found the left side much swollen and the pain had considerably increased, but on the third day the pain was greatly relieved and at the same time the urine became for the first time deeply stained with blood and he observed a number of small blood-clots in the urine. The hæmaturia continued for over a week when he sought admission to the hospital. Previously to the accident he had never noticed any blood in the urine. When he was admitted the bladder was found to be filled with blood-clot, so that a catheter required to be passed and the bladder washed out. The bleeding continued until April 10th when it suddenly ceased without any recurrence of the swelling or pain in the left lumbar region.

In the more severe lacerations of the kidney the urine is usually highly coloured and scanty and blood appears in the first quantity of urine passed after the accident. The hæmaturia may not be constantly present and may vary in amount from time to time or it may not appear at any time in the whole course of the case; consequently its absence must not be taken as an indication that the kidney is free from injury. Supposing the ureter to be completely torn across or the kidney divided through nearly its whole thickness the great probability is that the blood will escape into the tissues surrounding the injured organ rather than by the ureter and bladder.

CASE 5. *History of fall of over 60 ft. producing large scalp wound, punctured wound between the right scapula and spine, compound fracture of the left leg and rupture of the liver and kidney.*—The patient was admitted to the Glasgow Infirmary on March 20th, 1896, suffering very severely from shock. About 11 P.M. on the previous evening he fell down the shaft of a mine, about 66 ft. deep, into water about 3 ft. or 4 ft. in depth. On examination the patient was found to have sustained a long scalp wound on the back of his head, a punctured and lacerated wound between the right scapula and the spine, a wound over the right elbow, and a compound fracture of the left leg three inches below the knee, which exposed the bone for three or four inches. Although suffering severely from shock at the time of admission he gradually improved during the following day, but complained very much of pain in the small of the back. 30 oz. of urine were passed on the 21st and it contained only a small quantity of blood. On the morning of the 22nd he suddenly became much weaker, the pulse failed rapidly, his respirations became more laboured, and death occurred about 1 P.M.

The post-mortem examination showed, beyond the external injuries above mentioned, a slight rupture on the convex upper surface of the liver, some sub-serous ecchymosis at the cardiac end of the stomach, and the adipose capsules of both kidneys were filled with blood which had escaped through large ruptures of the renal tissues; no blood had escaped into the peritoneal cavity. On the other hand, hæmaturia may be a prominent symptom after an accident without the kidneys themselves being injured in any way. I well remember a case which came under my notice many years ago while I was resident assistant in the Western Infirmary, Glasgow.

CASE 6. *Injury to the pelvis and right lumbar region; severe hæmaturia, thought at first to be renal afterwards proved to be from the neck of the bladder.*—The patient, a lad, aged fifteen years, by occupation a carter, was leading his horse and a heavily-laden cart up a steep hill. Walking backwards in front of the horse he suddenly slipped and one wheel of the cart passed obliquely over his pelvis and right lumbar region

[4] Newman: Surgical Diseases of the Kidney, p. 312.

Digitized by Google

without causing any fracture of bone. When brought into the Western Infirmary he complained of great pain in passing urine, which was highly stained with blood. For some time the hæmaturia was believed by the late Dr. J. G. Lyon to be due to a rupture of the kidney, but on more careful examination it became abundantly evident that the escape of blood arose from an injury of the urethra close to the neck of the bladder, which led finally to the formation of a urethro-rectal fistula.

CASE 7. *Fall producing severe injury in the right lumbar region followed by renal pain and hæmaturia lasting for three days; apparent recovery in one month, followed by return of pain, sense of weight in the right lumbar region, and physical signs of moveable kidney.*—A man, aged twenty-seven years, a fireman, was admitted into the Glasgow Royal Infirmary on Nov. 19th, 1897. He stated that in the previous July he fell from a ladder and struck his right side just below the ribs; the height of the fall was only about 3 ft. and at the time the injury appeared so trifling that he continued his work for three hours thereafter; but on walking home from his work he began to suffer from severe pain just below the right ribs in the lumbar region. It was aching in character and increased by deep inspiration, coughing, or bending forward the body. The first quantity of urine passed contained blood but no blood-clots were observed. The hæmaturia continued for three days only, after which the urine became quite clear. After remaining ten days in bed the pain became less severe, but occasionally while at work it recurred and did not finally disappear until about a month after the injury. Five months after the accident, while lifting a heavy weight, he felt as if something had given way in his back and shortly the pain became so bad that he was forced to give up his work and take to bed. The pain on admission to the hospital was very severe and occasionally passed down the right thigh as far as the knee. On examining the abdomen a distinct right moveable kidney was discovered even although over it the muscular resistance was increased. In the lumbar region on the right side the percussion was unduly dull, even when the patient was lying upon his face and the right kidney pressed forwards. The urine was strictly normal in all respects.

While these cases sufficiently illustrate the hæmaturia produced by direct injury I have seen other cases where slight indirect violence has been followed by the appearance of blood in the urine for the first time. It is not to be concluded in such cases that the traumatism is the only cause of the hæmorrhage; pre-existing disease may not up till the time have shown itself by a hæmaturia, but a hæmorrhage may be brought on by a slight direct or indirect blow, as, for example, there may be a stone in the kidney, or a tumour, or chronic Bright's disease. The patient receives a blow in the lumbar region, he falls on his buttock, or he sustains a sudden strain from lifting a heavy weight, then suddenly he has a sharp pain in the renal region or feels as if "something had given way," and the first urine he passes thereafter contains blood. Here the injury has been the immediate exciting cause only, but the circumstance that a hæmaturia has been brought on by so trivial an injury makes one very suspicious of the presence of a soft malignant tumour either in the kidney or in the bladder.

CASE 8. *Carcinoma of the right kidney; first symptom profuse hæmaturia after a slight fall followed by great pain in the renal region and the passage of large blood-clots. Subacute tubular nephritis.*—The patient, aged sixty-one years, was seen by me three months before his death in December, 1885. The history given by his family attendant (the late Dr. Robert Smart) was that he tripped going downstairs and fell, landing upon his left side and buttock. No renal pain was experienced at the time of the accident, but two hours afterwards he passed urine containing a considerable quantity of blood and early the next day severe pain was experienced in the right lumbar region. This was coincident with the passage of a large quantity of blood-clot and some blood. On the evening of the day after the accident the bladder was filled with blood-clot so that a large catheter required to be passed and the bladder washed out with boric solution. There was no renal colic, but the patient experienced a diffuse and intense pain in the lumbar region, which was increased by deep pressure; rest in bed and the administration of hazeline had no effect upon the bleeding. The bladder was washed out with a solution of boric acid twice daily. Morphia suppositories were given and after eight days the pain somewhat subsided and the hæmaturia diminished. The temperature rose to 102° F. in the evening and oscillated between that and 99·5° during the next fortnight, when a second profuse hæmaturia occurred, which greatly weakened the patient. The urine had a specific gravity of from 1011 to 1015 and an alkaline reaction; it contained more albumin than was represented by the blood present and the deposit was composed of mucus, triple phosphates, blood, leucocytes, large epithelial cells, and granular and epithelial tube-casts. The question of an operation was considered, but in the circumstances it was not deemed advisable. The patient died three months after the onset of the first hæmaturia and at the post-mortem examination a large fungating carcinoma was found occupying the pelvis of the right kidney. Both kidneys were soft and considerably enlarged and the mucous membranes of the pelves were in a state of acute catarrh and contained some muco-purulent material and on microscopic examination the tissue of the kidney presented the characteristic appearances of subacute tubular nephritis. In this case probably the necessary catheterism of the bladder facilitated the fatal termination, but we had only the choice between two evils.

(b) From calculus.—I have already referred to some of the features which distinguish hæmaturia arising from renal calculus and that due to other causes, but still there are points which require attention. The most obvious characteristics of this form of hæmaturia are that the bleeding is seldom profuse or obstinate. The blood is generally light in colour and the hæmorrhage is as a rule brought on by sudden movements or active exercise, and it is associated generally with severe colicky pain. These circumstances when accompanying or determining the hæmaturia give the symptom its special value. In cases of renal calculus without suppuration, especially if the stone be impacted in the renal substance, the symptoms are not marked; indeed, the only indication of disease may be occasional slight renal pains, with or without hæmaturia, or severe pain may exist for a time and then disappear for a long period. It is in such cases that the diagnosis of renal calculus is difficult, sometimes quite impossible. There may be renal pain, frequent micturition, slight hæmaturia, or even the presence of small quantities of pus in the urine, from an undue increase in the free acid in that excretion or from oxaluria. The habitual deposit of uric acid or oxalate of lime in urines of high specific gravity is often associated with dyspeptic, nervous, and other symptoms strongly suggestive of renal calculus. These may last for long periods, but if suitable treatment be adopted they usually disappear. On the other hand, considerable, sometimes enormous, stones may be discovered in the kidney after death, although no renal disturbance had been known to exist at any period during the life of the patient. This is not uncommonly observed in hospital practice. Under such circumstances the want of knowledge may reasonably be attributed to the carelessness of the patient, but such an explanation cannot be urged for a case which Dickinson describes. A renal calculus composed of phosphates of magnesia and ammonia, weighing 7½ oz., was taken from the body of a daughter of Sir Richard Steele, in whom during life no symptoms indicated its presence. In uncomplicated cases of renal calculus the pain is generally dull or may only amount to a sense of weight in the loin on the affected side. It is, as a rule, inconstant, absent while the patient is at rest but aggravated on any movement of the body, but especially by jolting movements, such as jumping, riding, driving, &c. The pain may also vary with posture, one attitude being generally associated with increased discomfort, while another may bring relief. The unpleasant sensations just referred to are for the most part limited to the affected side, they may, however, extend along the course of the ureter to the perineum, the testicle, or down the thigh; but while this is so the pain may pass over or even be limited to the opposite renal region. In non-suppurating cases of calculus, hæmaturia is one of the most important symptoms. But while, on the one hand, it may be true to state that of all causes of hæmorrhage from the kidney calculus is the most common, on the other hand a calculus may occupy the kidney without at any time causing the patient to lose a perceptible quantity of blood. Although constantly present or oft repeated, hæmaturia from calculus is rarely so profuse as to cause marked anæmia. Perhaps the most characteristic feature of calculous hæmaturia, as distinguished from other forms, is its dependence upon movements of the body. Sometimes the appearance of blood or an increase in the hæmorrhage does not

Digitized by Google

immediately follow exercise, but only shows itself after some hours or even days.

CASE 9. *Renal uric acid calculus; exercise causing immediate pain and hæmaturia the following day; no blood-clots in the urine.*—The patient, a woman, aged fifty-eight years, in 1888 consulted Professor (now Sir) William T. Gairdner, who sent her to me. She had suffered from violent colicky pain in the right renal region for the previous six years. At first the attacks were slight, and were always brought on by some active exercise. They did not recur oftener than once in six or eight months, but latterly the recurrences of pain were more frequent, and were accompanied by hæmaturia; usually, however, the quantity of blood was small in amount and the urine cleared up very soon after the patient procured complete rest in bed. So long as she remained at rest the pain did not trouble her and the urine remained clear; but if she took active exercise it was certain to bring on an attack of pain, which was followed by hæmaturia in from eighteen to twenty-four hours. This delay in the appearance of blood was frequently observed. No blood-clots were seen in the urine at any time, and the urine passed at the onset of the attack and for several hours following was clear and of low specific gravity, from 1006 to 1008.

The circumstance that no blood-clots were seen in the urine seems to indicate that the non-appearance of blood in the urine till the day following the onset of pain was not due to obstruction of the ureter by coagulum. The most reasonable explanation of such cases seems to be that the irritation of the calculus in the pelvis or at the entrance of the ureter induced a reflex inhibition of the function of the affected kidney only, either by producing a spasm of the walls of the ureter, or contraction of the small renal arteries, and that this spasm passing off was followed by an undue relaxation of the capillaries, a passive hyperæmia and transitory hæmorrhage following. Most usually, unilateral obstruction, such as is produced by the presence of a calculus in one ureter causes reflex inhibition of both kidneys and complete anuria. Irritation of the uinary bladder, as manifested by frequent and sometimes painful micturition, is not an uncommon accompaniment of renal calculus—so much so that I have seen this disease mistaken for cystitis or suspected to be vesical calculus. This mistake is, however, more apt to occur when the renal stone has caused suppuration. On account of the intimate relationship which exists between the nerve-supply of the kidneys and that of the alimentary canal, hæmaturia and renal pain, especially if intense, are accompanied by more or less gastric disturbance, varying in degree from the mildest attacks of nausea to the most violent vomiting of bilious matter, flatulence, and gastrodynia. When the renal calculus has given rise to or is associated with suppuration the symptoms are generally distressing and persistent. The amount of irritation in the kidney, in the renal pelvis, and in the ureters caused by a concretion depends largely upon its nature and situation. The rougher, heavier, and more freely moveable a calculus is, the higher will be the degree of irritation, as manifested by symptoms of pyelitis or pyonephrosis superadded to those of calculus. On the other hand, the effect of prolonged rest in the treatment of renal calculus is well recognised. The following case is a good illustration of it.

CASE 10. *Constant dull pain of four years' duration, occasional attacks of hæmaturia from the right kidney, sometimes very profuse after exercise; nephro-lithotomy advised but refused; the symptoms cured by rest in bed.*—A man, aged thirty-five years, consulted me at the Glasgow Infirmary and was admitted on Nov. 15th, 1892. Two and a half years prior to admission the patient was playing lawn-tennis, when he suddenly strained himself, and within a few hours he passed a large quantity of dark, mahogany-coloured urine, but this was not accompanied by any pain. Six months after this he had a recurrence of the hæmaturia, associated with an acute attack of renal colic, which, however, only lasted for a short time, but after the first attack he had recurrences both of the hæmaturia and pain every five or six weeks. On admission physical examination elicited no abnormal conditions beyond increased resistance in the right lumbar region. The urine was highly coloured, of specific gravity 1028, acid, containing a deposit of mucus and a slight trace of albumin, but no blood or pus. Four days after admission the patient had an acute attack of hæmaturia and of severe pain which lasted from 6 A.M. till 9.30 A.M., when he was placed under chloroform and the bladder was explored with the cystoscope. The examination revealed blood issuing from the right ureter in small quantity, and the orifice of the ureter was occupied by a clot. The circumstances of the case seemed to warrant a diagnosis of renal calculus and the patient was advised to have it removed by operation. This, however, he refused, and so complete rest in bed was ordered. The patient was kept at absolute rest for four weeks, and during that time he had no recurrence of the pain or of the hæmaturia. He remained in bed for other six weeks after leaving the infirmary, and on March 21st, 1897, he reported that he had had no recurrence of the pain or the bleeding since he left the hospital on Dec. 16th, 1892.

(To be continued.)

TWO CASES OF OBSTRUCTION BY BAND; THE ONE CHRONIC, THE OTHER ACUTE.

BY HERBERT W. PAGE, M.C. CANTAB., F.R.C.S. ENG.,
SURGEON TO ST. MARY'S HOSPITAL.

EACH of these cases had special features of interest which seem to make them worthy of record—the first by reason of the position, strength, and exceeding tenuity of the obstructing band, and the second because of the unusual amount of blood-stained peritoneal effusion and the acutely dangerous condition of toxæmia from which the patient was rescued. I am indebted to Mr. F. W. Summer for the notes of the first case which was that of a married woman without children, who was admitted to St. Mary's Hospital on Jan. 15th, 1896. She had previously been treated by Mr. Archer Wood, of Dulwich, from whom it was learned that four years before she had been under his care for a month suffering from some difficulty in the action of her bowels, with occasional passing of a small quantity of blood. The attack, however, ceased, and until within three months of her coming to the hospital she had continued well. The same symptoms then returned. She had through life been healthy and had never to her recollection been laid up with any abdominal disorder. A well-nourished woman, thirty-eight years of age, as far as appearances went she had nothing the matter with her and her aspect was altogether unlike that of a person suffering from malignant disease. There was no abdominal distension, but invariably before action of the bowels she suffered somewhat severe pain to the left of the umbilicus which was relieved by firm pressure with her hand, a manœuvre which experience had taught her was of use in securing action of the bowels. Evacuation of the bowels was thus always a matter of pain and difficulty, but she had no vomiting and beyond a little mucous discharge and slight laxity of the motions there was nothing to call for special remark. Nothing was to be felt *per rectum* and the result of abdominal examination on Feb. 1st under an anæsthetic was equally negative. Anxious herself to be quit of the trouble and in the belief that there must be some cause of partial obstruction in the lower bowel which could in all probability be relieved, exploration was resorted to on Feb. 5th. The abdomen was opened in the left linea semilunaris and an inch or so above the termination of the descending colon there was seen to be a deep sulcus which on closer investigation was found to be produced by a band running transversely across the gut. The finger-nail was passed under it with the object of tearing it, but this proved impossible, for the band was stretched across the bowel with the tightness of a violin string and the knife was necessary for its division, when it snapped with a distinct twang. There were no other bands or adhesions in the neighbourhood and no light was thrown on the origin of this peculiarly tense, unyielding cord. It must, however, have been a thing of old formation and in all probability had its beginning at the time of her first short illness four years before. The affected region of the gut was free from congestion or structural change. It had no mesocolon. The result of the operation was to rid the patient immediately of all her symptoms, and from inquiry in the course of the present year we learned that she had enjoyed good health since leaving the hospital on March 10th, 1896, the

Digitized by Google

wound having then soundly healed. It is difficult to surmise what may have been the precise origin of this unusual band, for there had been no history of pelvic trouble and the band itself lay entirely outside the pelvis. I have never seen an abdominal band at all as firm as this, and it was a fortunate event for the woman that it was divided before the bowel had been itself damaged. The history shows how indefinite and obscure were the symptoms and how operation alone could have relieved them. So fine, however, was the band, that had it not been for the sulcus in the bowel it might perchance have been missed—an accident which I know to have occurred in another case with somewhat like symptoms, unfortunately postponing thereby a second operation for the relief of complete obstruction until it was too late. The practical lesson to be learned from the case is thus sufficiently obvious.

CASE 2.—This case was one of the most acute obstruction with symptoms of extreme urgency. A man, aged fifty-nine years, was admitted to St. Mary's Hospital on March 8th, 1898. On the early morning of the 7th he was seized with great pain at the umbilicus while at stool—pain which rapidly became so much worse that he was obliged to leave his work and send for a medical man. In the afternoon he vomited frequently. After 10 A.M. he passed neither fæces nor flatus. On admission to the hospital at midday of the 8th he had a most anxious, ghastly expression; his face and lips were blue, his mouth was parched, he had intense griping pains all over the abdomen, he was well-nigh pulseless, and was almost continuously sick. The abdominal wall was rigid, but there was no marked distension. Nothing could be felt on palpation. The nature of his symptoms admitted of no doubt and he was taken at once to the theatre. The abdomen having been opened in the middle line, systematic examination of the bowel from below upwards ultimately led to the discovery of a coil of jejunum some six inches in length, of a deep plum colour, constricted by a fine band three or four inches long, and running from omentum to omentum. It was easily torn through with the finger and did not bleed. Flatus immediately passed onwards into the empty gut below. The coil of ensnared bowel was smooth and free from lymph—there was indeed no effusion of lymph anywhere—and there was no fear that it would not perfectly recover itself. So much and no more would have been necessary in the way of operation had not the peritoneal cavity contained a large quantity of blood-stained serum—so much, in fact, that it was deemed absolutely essential to remove it, and this was forthwith done by washing out the cavity with a saline solution. Just as a hernial sac is sometimes found to contain blood-stained serum when bowel has been strangulated within it, so here the peritoneum took the place of a hernial sac into which unusual quantities of blood-stained serum had been effused. The wound was closed in the usual way, and thereafter the patient made steady progress to recovery. His course throughout gave little or no anxiety; the vomiting soon ceased and his bowels were in due time moved, his only trouble being the most intense thirst for three or four days after the operation, due in no small measure, it may be conceived, to the loss of fluids both by the vomiting and the peritoneal effusion. He was discharged on May 5th. For the notes of this case I have to thank Mr. Hussey.

The operation was in this case singularly free from difficulty because of the fact that the constricted bowel was high up and the greater portion of small intestine was flaccid and empty. But the site of the strangulation no doubt determined the initial severity of the symptoms, which in their turn contributed to that which was the most prominent feature in the case—the extraordinary amount of peritoneal effusion. This, again, in turn conduced to the serious condition of the patient, which was clearly one of acute toxæmia from which death was imminent. The peritoneum presented none of the grosser visible signs of peritonitis, but the man was nevertheless dying, surely not from the mere fact that a short length of bowel was ensnared by a band but because doses of poison developed in his own peritoneum—and in all probability of the most virulent kind—were being rapidly absorbed into his system. There was never a more striking case. "There is about the patient who is dying of peritonitis every suggestion of a poisoned man. He lies in bed prostrate, with gaunt cheeks and sunken eyes. There is a look of unceasing anxiousness in his face and a sense of hopeless unquiet in his movements. The hands, which wander with pathetic restlessness over the bedclothes, are cold and damp. The tongue is that of a man who is dying of thirst. There is constant vomiting. The breathing is laboured and accompanied with faint sighs and groans, and the countenance is ashen and livid." This is the picture drawn by Treves in his lectures on Peritonitis,[1] and it is eminently suggestive of death by poison. To clear away the source of the poison in the peritoneum must, then, be the surgeon's aim, and it may with truth be said that there is probably no condition in which it is so essential to wash and cleanse the peritoneal cavity of any effusion there may be in it, or in which it is so necessary to disregard, and not be misled by, the absence of the grosser indications of "peritonitis" if the best is to be done for the patient in a case like this at the time of operation.

THE VALUE OF ANTI-STREPTOCOCCIC SERUM IN THE TREATMENT OF SOME PATHOGENIC INFECTIONS.

BY NATHAN RAW, M.D., B.S. DURH., F.R.C.S. EDIN.,
MEDICAL SUPERINTENDENT, MILL-ROAD INFIRMARY, LIVERPOOL.

So many conflicting statements have been made in the medical journals of late regarding the efficacy and real value of anti-streptococcic serum that I determined to give it an extended and thorough trial in those diseases which were found on examination to be due to infection by the streptococci. In THE LANCET of Feb. 19th, 1898, I recorded a case of puerperal septicæmia in which the patient's life was, in my opinion, saved by this treatment and I then sounded a note of warning against the indiscriminate practice of injecting all cases of septic infection with this powerful remedy. From the very nature of things the serum can only be of service in streptococcal infections and ought never to be used until either the microscope or bacteriological examination has shown streptococci to be present in the blood or discharge. The cases under my care in which the serum has been used are 11 in number—namely, 4 cases of puerperal septicæmia, 2 cases of septic cellulitis, 2 cases of mastoid disease with septicæmia, 2 cases of erysipelas, and 1 case of puerperal sapræmia.

CASE 1.—A married woman, aged twenty-two years, a primipara, was admitted to the infirmary on Oct. 31st, 1897, suffering from puerperal septicæmia. She had been delivered 15 days previously, having been attended by a midwife. The patient's temperature was 106° F. and the pulse was 146. She was quite unconscious and wildly delirious. I curetted the uterus, removing a large quantity of placenta and stinking débris. On examination of this it was found to be swarming with streptococci which were also found in the blood. Injections of serum (20 c.c. as a dose) were given at intervals with marked effect. The temperature was reduced, the delirium abated, the patient became conscious, and the pulse was reduced in rate and altogether much improved. In all she had 60 c.c. of serum in four injections and made an excellent recovery.

CASE 2.—A woman, aged thirty years, was admitted to the infirmary on Nov. 8th. She had been confined of a still-born child on Oct. 28th, having been attended by a midwife. The labour was prolonged, lasting a week; 3 days later she became delirious. On admission the temperature was 103° F. and the patient had all the symptoms of puerperal septicæmia. Microscopic examination showed that streptococci were present both in the blood and in the discharge from the uterus. On Nov. 25th the patient was put under chloroform and the uterus was scraped out and 10 c.c. of serum were injected; the temperature dropped to 101° and she felt much better. She, however, developed septic pleurisy and died on Dec. 5th.

CASE 3.—A girl, aged fifteen years, was admitted to the infirmary on Dec. 30th, 1897, with a high temperature (105° F.), loss of consciousness, and acute delirium. She had a purulent discharge from the left ear and all the symptoms of mastoid abscess with meningitis. On the 31st the mastoid antrum was cleared of a lot of offensive pus and I made a free communication between the middle-ear and external

[1] Lettsomian Lectures, 1894, p. 8.

Digitized by Google

meatus. The pus from the middle-ear was full of streptococci. 20 c.c. of serum were injected with an excellent result, the temperature dropped in a few hours, the headache was better, the skin was moist, and the pulse was reduced. She, however, developed septic pleurisy and died on Jan. 1st, 1898. At the post-mortem examination it was found that the lateral sinus and internal jugular were thrombosed and contained stinking thrombi.

CASE 4.—A girl, aged nineteen years, was admitted to the infirmary on Jan. 26th, 1898, with a temperature of 105° F., suffering from a most acute attack of erysipelas which involved the head, neck, and chest. The temperature remained between 104° and 105° for 5 days and the girl was in a very critical condition. Examination showed that the blood was swarming with streptococci. 20 c.c. of serum were given on Jan. 30th with a most astonishing result. The temperature dropped to 100° in 5 hours and the patient was more conscious and felt relieved. The temperature again rose to 105° on the next day and another 20 c.c. of serum were given, with the result that it dropped in five hours to normal. It again rose next day to 104°, when 20 c.c. of serum were given, bringing down the temperature to 101° and the pulse from 140 to 110. The patient had another injection on Feb. 2nd of 20 c.c. of serum, after which the symptoms subsided and she made an excellent recovery. The patient had in all 80 c.c.

CASE 5.—A woman, aged thirty-five years, was admitted to the infirmary on Feb. 19th with septic cellulitis of the hand and arm extending to the elbow. It had a foul and gangrenous smell and was rapidly extending. Examination of the pus showed the presence of streptococci. Under chloroform I made free incisions and removed all the sloughing material and at the same time injected 20 c.c. of serum into the affected arm. The result was magical; the arm quickly quieted down and the patient made a good recovery with a useful arm.

CASE 6.—A woman, aged forty-six years, was admitted to the infirmary with septic cellulitis of the arm following an injury by a rusty nail. She was extremely ill, the wrist-joint was suppurating, and she had septicæmia. I laid open the joint and incised the arm and injected 20 c.c. of serum. She improved considerably, but eventually succumbed to an attack of septic pericarditis.

CASE 7.—A girl, aged seventeen years, was admitted to the infirmary on March 10th, 1898, with all the symptoms of mastoid abscess and meningitis. Her temperature was 104° F. and she had a fœtid discharge from her left ear on March 11th. I trephined the mastoid antrum and made a free communication with the external meatus, clearing out a lot of stinking pus. At the operation I injected 20 c.c. of serum. On the following day she was conscious and her temperature dropped to normal. She afterwards had three injections of 10 c.c. of serum each and although she had a prolonged attack of meningitis she made an excellent recovery. Her blood contained streptococci.

CASE 8.—A woman, aged thirty years, was admitted to the infirmary on March 19th suffering from puerperal septicæmia. She had been confined a week previously of a child and attended by a midwife. The uterus was scraped out and 20 c.c. of serum were given three times, making in all 60 c.c. After each injection she was relieved, the temperature dropped, the pulse became slower, and her headache and pain were relieved. She developed, however, septic pleurisy and pericarditis and died on March 24th.

CASE 9.—A woman, aged thirty-four years, was admitted into the insane wards of the infirmary on April 17th with puerperal mania. She had a temperature of 102° F., which rapidly rose to 105°, with all the symptoms of septicæmia. Under chloroform I curetted the uterus and intra-uterine douches of mercuric chloride were given. Plate cultures were made of the blood and uterine discharge which showed an almost pure cultivation of streptococci. 10 c.c. of serum were given on the 21st with a good result. She had numerous complications in the form of abscesses and infective periostitis of the femur, which were opened and drained under anæsthetics. In all she had 90 c.c. of serum, which in my opinion saved her life, as I have never seen a more complicated case.

CASE 10.—A woman, aged twenty-five years, was admitted to the infirmary on May 26th with all the symptoms of puerperal septicæmia with profound anæmia. She was delivered of a child a week before admission with placenta prævia. On admission her temperature was 105° F. and she was in a most serious condition. Under chloroform I curetted the uterus and removed nearly 2 oz. of stinking placenta and débris. On making plate cultivations of both the blood and uterine discharge no streptococci could be found, but numerous staphylococci, both aureus and albus; before the result of the bacteriological examination was known I injected 20 c.c. of serum (Pasteur's). The good result noted in the previous cases was not seen here, the temperature remained high and no further injections were given. The patient lingered until June 21st, when she died from septic pleurisy and thrombosis. Post mortem a very careful bacteriological examination was made of the organs. Cultivations on Petri dishes were made from the uterus, kidneys, and lungs, and all showed a complete absence of streptococci, but numerous staphylococci and bacilli coli communes were present. The uterus was found to be almost smooth and she had septic pleuro-pneumonia.

CASE 11.—A woman, aged fifty-two years, was admitted to the infirmary on June 24th with an acute attack of erysipelas, the temperature being 105° F. She was given 20 c.c. of serum with a most excellent result and completely recovered.

The above series of 11 most acute and severe infections by streptococci show 6 recoveries and 5 deaths. This is, I admit, not a very large percentage of recoveries, but it must be borne in mind that only the most acute and dangerous cases were submitted to the treatment. The most difficult part of the treatment is to determine the exact nature of the infection, whether it is due to the various forms of streptococci, or to staphylococci, or to a mixed infection of all these organisms. The bacillus coli communis is repeatedly found here, rarely alone, but generally with staphylococcus aureus; whether or not it is the same organism as the bacillus pyogenes fœtidus is a matter of uncertainty. My routine practice now is to at once submit the blood or discharge from any case of acute infection to a bacteriological examination in the laboratory, and if the presence of streptococci is demonstrated clearly to at once inject the serum. If the streptococci are not found the serum can be of no possible service, as was well shown in Case 10.

Much has yet to be done to elucidate the exact bacteriology of the various forms of sepsis and especially to separate and individualise the streptococci. The Pasteur Institute have succeeded in obtaining an anti-streptococcic serum by injecting pure toxins, thus placing it on the same basis as anti-diphtheritic serum, but at present the composition is a secret. If this is accomplished I feel sure it will be a great step in advance in the treatment of pyogenic infections. From a careful and prolonged use of the serum I feel convinced of its efficacy in the streptococcal infections such as puerperal septicæmia, septic cellulitis, erysipelas, and septic meningitis from middle-ear disease. The serum I now use is supplied by any druggist and is obtained from the Pasteur Institute in fluid form, as I find it more pure and free from errors in filtration. I have never seen any bad symptoms from the use of the Pasteur serum if obtained comparatively fresh and injected with antiseptic precautions. The dose I prefer is 20 c.c. In conclusion, I have to express my thanks to my colleagues, Mr. German and Dr. Christophers, for their useful assistance.

Liverpool.

A NOTE UPON A CASE OF ABDOMINAL SECTION IN WHICH STERILE BROTH WAS INJECTED INTO THE PERITONEAL CAVITY PREVIOUSLY TO OPERATION.

BY J. W. WASHBOURN, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE LONDON FEVER HOSPITAL; ASSISTANT PHYSICIAN TO GUY'S HOSPITAL, &C.

DR. H. E. DURHAM, in an interesting paper upon the Clinical Bearing of some Experiments on Peritoneal Infections,[1] suggested a preliminary treatment of the peritoneum in operations upon the abdomen when there is a risk of contamination ensuing. The treatment he recommended

[1] Transactions of the Royal Medical and Chirurgical Society, vol. lxxx., Part II., p. 191.

Digitized by Google

was the preliminary injection of some substance which would increase the "local general resistance" of the peritoneum. This recommendation was based upon the experimental work of Issaef, who showed that the injection of such substances as sterile broth or nucleinic acid into the peritoneal cavity of guinea-pigs 24 hours before inoculation with the cholera vibrio protected the animals from death, while the injection of "cholera serum" was still more potent. Dr. Durham confirmed and extended these observations and drew attention to the fact that the most efficacious substance to employ was the serum of animals immunised to the microbe used for subsequent inoculation. From a careful examination of a number of cases of death after abdominal section he also showed (1) that various kinds of bacteria might be the cause of death after abdominal section, but that the streptococcus pyogenes was the most frequent; and (2) that death after abdominal section was often attributed to collapse or shock when it was really due to bacterial infection. From these considerations Dr. Durham suggested a preliminary treatment of the peritoneum in certain cases of abdominal section, and he thought that the antistreptococcic serum was perhaps the best substance to employ. As this was only a suggestion which had never been carried out the notes of the following case in which the method was employed may be of interest, if for no other purpose, to show that in certain cases, at any rate, it is practicable.

The case was that of a child, aged eight months, who was admitted into Guy's Hospital at midday on May 15th, 1898, for intussusception. The symptoms, which commenced twenty-five hours before admission, consisted of abdominal pain, vomiting, and the passage of blood *per rectum*. No tumour could be felt. An attempt to reduce the intussusception by the injection of milk into the rectum was immediately made. During the evening the patient appeared to be comfortable and it was hoped that the intussusception had been relieved; but the next day all the symptoms had returned. At midday on May 19th an anæsthetic was administered and milk was again injected into the rectum. It was considered that in the event of the injection being unsuccessful an abdominal section would be required within the course of the next twenty-four hours and that the preliminary treatment of the peritoneum recommended by Dr. Durham was indicated. With this object 5 c.c. of sterile broth were injected into the peritoneal cavity with strict aseptic precautions while the patient was still under the anæsthetic. The injection was easily performed in the following manner. The abdominal wall was pinched up into a fold between the finger and thumb of the left hand and the fold was transfixed with the needle of the syringe. On loosening the grasp with the finger and thumb the fold sprang back, leaving the point of the needle in the abdominal cavity. On the 20th, the symptoms continuing, Mr. Dunn, who kindly saw the patient, opened the abdomen and attempted to reduce the intussusception. As the state of the gut prevented the reduction of the last part of the intussusception it was brought out of the wound and a Paul's tube was inserted. On the 21st the abdominal symptoms had subsided and the patient appeared better, but towards the evening he became collapsed and died at 1 A.M. on the 22nd. At the post-mortem examination the wound looked healthy and there was no evidence of peritonitis. All the organs were normal.

Cavendish-place, W.

A CASE OF PUERPERAL SEPTICÆMIA WITH SUBNORMAL TEMPERATURE THROUGHOUT.

BY JAMES J. HARDING, L.R.C.P. & S. IREL.

AT 9 P.M. on Feb. 28th, 1898, I was sent for to attend a woman, aged forty years, who was in her fifth confinement. She was instrumentally delivered of her first three children. Her fourth labour was easy and uneventful (probably premature). All the children survived their birth. I was informed by the nurse that the membranes had ruptured on the morning of the 25th at 2.30 A.M. The patient was an extremely anæmic woman; her pulse was weak at 120 and her temperature was 97° F. The os was dilated and the head, in the first position, was engaged high up in the brim. The uterus was in a state of weak tonic contraction. The fœtal pulsations were good at 140 and were heard below and to the left of the umbilicus. The sacral promontory was easily reached with the index finger, giving as nearly as I could calculate a conjugate of 3¼ in. I had some difficulty in delivering with forceps an asphyxiated child, who after the use of Schultz's artificial respiration, baths, &c., ultimately came to. The placenta and membranes were easily expressed entire. She had no hæmorrhage. After washing out the uterus with a 1 in 3000 sublimate solution and injecting subcutaneously $\frac{1}{100}$ gr. of ergotinin I left her with a pulse of 110, a temperature of 97°, and good uterine contraction. On March 1st the patient had had a restless night. Vomiting had set in at 4 A.M. and continued up to the time of my visit at 10 A.M. Urine had been passed freely but there had been no action of the bowels. The lochia were foul-smelling. The pulse was 150 and the temperature was 97°. I washed out the uterus with a 1 in 2000 sublimate solution; $\frac{1}{100}$ gr. of ergotinin and $\frac{1}{60}$ gr. of sulphate of strychnine were injected subcutaneously owing to the flabby state of the uterus and I gave a draught containing 15 minims of liquor opii sedativus. On visiting the patient in the evening I found that she had rested for two hours. The vomiting had ceased, only to return again, and this time was accompanied by diarrhœa. The lochia were abominably fœtid. The pulse was 130 and the temperature was 97·2°. I washed out the uterus with a 1 in 100 lysol solution and injected subcutaneously $\frac{1}{100}$ gr. of ergotinin and $\frac{1}{60}$ gr. of sulphate of strychnine. I gave an enema of Battley's solution of opium and starch (20 minims). On March 2nd the patient had passed a restless night. She still vomited but the purging had ceased. The lochia were unchanged; the urine was dribbling away, the bladder being full. The pulse was 110 and the temperature was 97·2°. I drew off the urine, washed out the uterus with a 1 in 100 lysol solution and injected subcutaneously $\frac{1}{100}$ gr. of ergotinin and $\frac{1}{60}$ gr. of sulphate of strychnine. I ordered an effervescing mixture containing 2 minims of dilute hydrocyanic acid to be taken every fourth hour. In the evening the vomiting was less but the diarrhœa had returned. The lochia were unchanged, being still horribly fœtid. The pulse was 120 and the temperature was 97·1°. The urine was drawn off. The mixture was stopped and was replaced by 1 minim of creasote in milk every third hour. The uterus was washed out with a 1 in 100 lysol solution and $\frac{1}{100}$ gr. of ergotinin and $\frac{1}{60}$ gr. of sulphate of strychnine were injected subcutaneously. The uterus was still flabby. An enema of liquor opii sedativus and starch (20 minims) was administered. On March 3rd the patient had passed a restless night. The pulse was 106 and the temperature was 97°. The vomiting and diarrhœa still continued, the lochia being as before. The creasote was continued. I washed out the uterus with a 1 in 100 lysol solution and injected subcutaneously $\frac{1}{100}$ gr. of ergotinin and $\frac{1}{60}$ gr. of sulphate of strychnine. I drew off the urine and tamponaded the uterus and vagina with iodoform gauze (10 per cent.). In the evening no change had taken place since the morning. The pulse was 110 and the temperature was 97°. All else was as before. I removed and replaced the tamponade and discontinued the creasote as it appeared to be doing no good, probably it was unabsorbed; otherwise the same treatment as before was carried out. On March 4th the patient was in the same condition as she had been on the previous day and the same treatment was continued. The temperature was still 97°. The uterus was again tamponaded. In the evening she was slightly weaker but otherwise as before. I removed the tamponade and did not replace it. The temperature was 97·1° and the pulse was 130. On March 5th she was dying. The temperature was 97 and the pulse could hardly be felt or counted. The patient died at 4 P.M.

At no time from the beginning did the temperature reach the normal. On referring to the few text-books at my hand I can find no such case mentioned. Galabin, Dührssen, Playfair, and Quain's "Dictionary of Medicine" all refer to fever as being the most noticeable of the symptoms. Even in the very virulent cases, such as this, where collapse setting in, the temperature sinks below 98° and remains so till death, an initial rise is,

Digitized by Google

according to those works, always apparent. No such rise occurred in this case nor were rigors noticed at any time. Abdominal tenderness was almost absent, as was also marked tympanites. I did not use anti-streptococcic serum nor did I curette as the symptoms were so profound from the first that I looked upon the case as hopeless and unlikely to be benefited by either. I have not mentioned dietetic treatment, stimulants, &c. They were of the usual description in such cases. The child was not weighed at birth, but on the tenth day it weighed 6½ lb.

I have to thank Surgeon-Captain O. L. Robinson, A.M.S., for kindly seeing the case with me and checking my observations, more especially the temperature observations, both with my own and a second thermometer.

Ballincollig, Cork.

AN INTERESTING CASE OF ANEURYSM.

BY J. H. MARTIN, M.R.C.S. ENG.,
DEPUTY INSPECTOR-GENERAL, ROYAL NAVY.

I BEG to send for publication in THE LANCET the following case, which presents the points of interest of (1) the patient being able to determine the exact moment of the rupture of the coats of the vessel and of (2) the rapid enlargement of the aneurysmal sac, which three days after the lesion was described as being "as big as a walnut" and on admission, eleven days later, was found to be of the size of a hen's egg.

The patient, a man, aged thirty-eight years, was received from H.M.S. *Royal Oak* on April 15th, 1898. The statement sent with him showed that on March 30th, three days before presenting himself at the sick berth, whilst blowing his boatswain's pipe he felt something "give" in his neck, and on examination an aneurysm of the left external carotid of the size of a walnut was discovered, and at the first opportunity he was sent to the hospital. On admission the patient, a spare man looking older than his years, was examined and the diagnosis of aneurysm of the left external carotid was confirmed; it was situated just above the bifurcation of the common carotid. The tumour was hard, smooth, and of the size of a hen's egg, clearly circumscribed, with eccentric, distensile pulsation over every portion which the fingers could reach, a little covered by the sterno-mastoid, which was displaced upwards and outwards. Being questioned the patient stated that a swelling in his neck suddenly appeared whilst he was blowing forcibly his boatswain's whistle, his head at the same time turning sharply over his right shoulder, giving in his neck the sensation "of the snapping of a piece of elastic," but he did not apply for treatment until the feebleness of his voice unfitted him for duty. He had afterwards suffered from a dry, metallic cough and the heart's action had become feeble and irregular. There was no valvular mischief; the arteries at the wrist were soft, compressible, and rather tortuous; there was no arcus senilis and the left pupil was contracted. There was no history of secondary syphilis and he appeared to have been a man of temperate habits and was married. He was placed in bed, put on a milk diet, and ordered twenty grains of iodide of potassium three times a day. Six days after admission he was put under chloroform and I cut down on the left common carotid, the vessel being ligatured with chromicised catgut above the border of the omo-hyoid. When the ligature was tightened pulsation in the sac at once ceased; there was a momentary contraction of both pupils, accompanied by a depression of circulation, pallor of the lips, and duskiness of the face and neck. The wound, practically bloodless, was closed with carbolised silk sutures and a piece of the finest drainage-tube was just inserted into the lower angle. He recovered slowly from the anæsthetic and the pulse remained feeble, intermitting about once in four beats. At 8 P.M. the patient suffered from intense pain over the whole left side of the head; he had vomited once. Three minims of hydrochlorate of morphia were injected. On April 22nd it was ascertained that he had had seven hours' sleep after the morphia and he was free from pain. There was no nervous symptom, but there was faint pulsation in the sac; the heart's action was weak and intermitting, and the left pupil was strongly contracted. On the 23rd the wound had firmly closed, the tube having slipped out. There was no pus and there was no pulsation in the tumour. On the evening of this day the patient suffered from severe headache over the left side of the head, and so he did again on the following evening, but at night he slept for seven hours. From April 25th the patient made uninterrupted progress. There was no headache, he slept all night, his appetite was good, the pulse under the administration of tincture of nux vomica had become stronger and regular, and the cough had ceased. On May 14th the patient was in his normal health. The aneurysmal sac was hard and was materially reduced in size; but the left pupil was still somewhat contracted. There was slight ptosis of the left eyelid, and the voice remained thin and boyish.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

GUY'S HOSPITAL.

A CASE OF WOUND OF THE INTERNAL PUDIC ARTERY; OPERATION; RECOVERY.

(Under the care of Mr. C. H. GOLDING-BIRD and Mr. L. A. DUNN.)

THE difficulty of applying a ligature to the gluteal, the sciatic, or the pudic arteries as they emerge from the sacro-sciatic foramen is very great and it sometimes happens that the proximal portion of the wounded vessel retracts into the pelvis so that it is almost impossible to reach the bleeding artery. In these cases it has been suggested to tie through an abdominal incision the internal iliac or the corresponding branch after the division of the trunk. Fortunately wounds of these vessels are rare and especially rarely is the internal pudic wounded in its very short course in the buttock, for it enters this region only to leave it almost immediately. Even in the perineum, where the artery is more exposed to injury, it receives much protection from its sheltered position under cover of the ischial tuberosity. For the notes of the case we are indebted to Mr. Victor E. Collins, house surgeon.

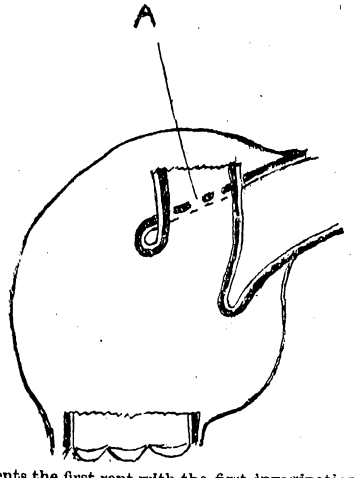
A man, aged twenty-five years, was admitted into Cornelius Ward, Guy's Hospital, on May 25th, 1898, for injuries to the right buttock, head, and left hand. The history of the accident was that whilst painting the patient fell through a glass skylight on to the floor below, a distance of about 16 feet. It was found that he had cut his head and injured his left hand. He was therefore promptly taken to the hospital and was at once admitted. The clothes and stretcher were saturated with blood. On admission he was very collapsed from hæmorrhage, the pulse at the wrist being almost imperceptible, and a hypodermic injection of brandy (10 minims) was immediately given. Examination revealed the presence in the right buttock of a large tender swelling, which was rapidly increasing in size and which was exquisitely tender to the touch. In the middle of the swelling there was a punctured wound which extended right down to the bone and there was smart hæmorrhage from this wound. In the trousers corresponding in position to the wound there was an L-shaped tear and a pointed piece of glass was found in them. There was a deep scalp wound on the summit of the cranium and two lacerated wounds on the dorsum of the left hand were observed. In the absence of Mr. Golding-Bird Mr. L. A. Dunn saw the case and decided upon immediate exploration in order to ascertain the cause of the hæmorrhage. It was thought that the gluteal artery had been wounded.

Digitized by Google

Ether having been administered a director was passed into the punctured wound and an incision about 6 in. in length was made in the direction of the fibres of the gluteus maximus, having its centre at the puncture. The wound was carefully deepened till the bone was reached, a considerable amount of blood-clot being turned out. Hæmorrhage was controlled by pressure forceps and the bleeding vessel was carefully sought for. It was then found that the internal pudic artery had been completely divided at the point where it crosses the spine of the ischium. The cut ends were ligatured with silk. This proved to be a matter of great difficulty owing to the depth of the wound. The wound was carefully cleansed, the muscles were approximated with continuous silk suture, and the skin was brought into apposition by interrupted salmon gut sutures. The patient made a good recovery and was discharged from the hospital on June 17th with the wound quite healed.

Remarks by Mr. COLLINS.—The case seems to be one of interest, firstly, on account of the rarity of such an accident, and, secondly, because of the difficulty of controlling the hæmorrhage owing to the depth at which the wounded vessel was situated. In conclusion I have to thank Mr. Golding-Bird and Mr. Dunn for their kindness in permitting me to publish the case.

YORK COUNTY HOSPITAL.



A CASE OF COMPLETE RUPTURE OF THE AORTA PRESENTING SOME EXTRAORDINARY FEATURES; NECROPSY.

(Under the care of Dr. R. PETCH.)

IN the very rare condition which is met with in the case reported below the length of time during which the patient survived is remarkable. Although there was a complete rupture of the aorta life was prolonged for more than five hours; this was only rendered possible by the attachment of the pericardium preventing the further effusion of blood. The explanation offered by Dr. Ashwin of the manner in which the vessel underwent such a curious invagination is very ingenious. For the notes of the case we are indebted to Dr. R. H. Ashwin, assistant house surgeon.

A man, aged fifty-six years, absolutely destitute and homeless, was observed to fall suddenly at 9 P.M. on April 20th while he was walking quietly on level ground. He immediately became unconscious and was taken to the York County Hospital, where he was admitted at 9.30 P.M. under the care of Dr. Petch. On admission he was in an extreme

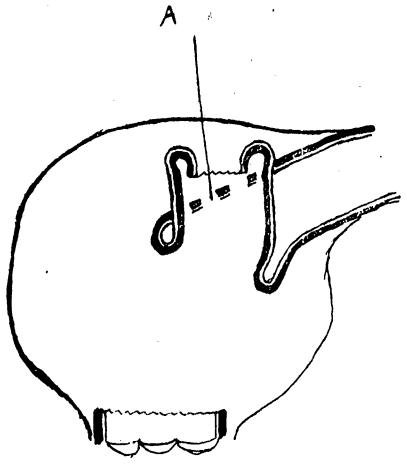


FIG. 1.

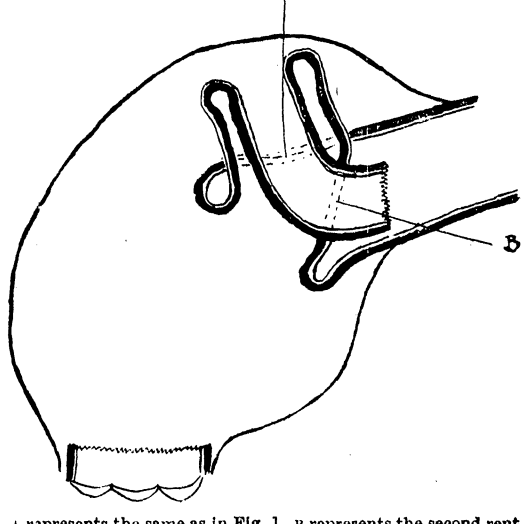
A represents the first rent with the first invagination passing through it.

state of collapse. The pulse was only just perceptible at the wrist, the skin was cold, clammy, and covered with perspiration, and the respirations were very infrequent and stertorous. There was also extreme rigidity of all the limbs with increased knee-jerks and an occasional spasm of the pectoral muscles drawing the upper arms in front of the chest. The pupils were dilated and did not react to light, but there was a sluggish conjunctival reflex. He had vomited whilst he was being conveyed to the hospital. From the extreme collapse, associated with rigidity of the limbs, the diagnosis of cerebral hæmorrhage was made. The patient was at once put to bed with plenty of hot bottles and under the influence of hypodermic injections of brandy and ether and the application of hot

FIG. 2.

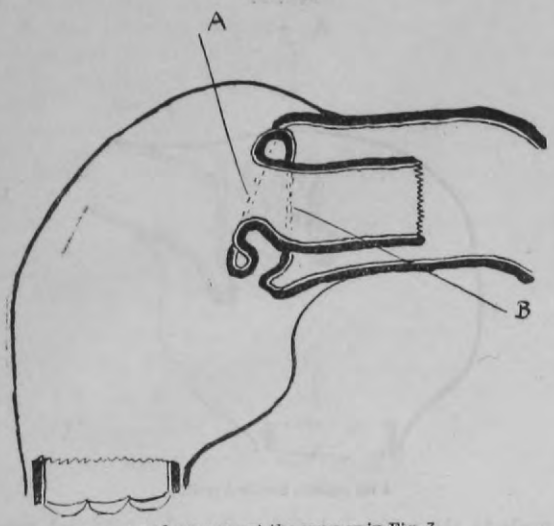


A represents the first rent.

flannels to the præcordial region the pulse improved considerably for a time. He vomited again whilst he was in the hospital, but there was no smell of alcohol or anything characteristic in the vomit. Death took place at 2.30 A.M., about five and a half hours after he fell, without his ever regaining consciousness.

Necropsy.—At the post-mortem examination it was found that the pericardium contained 6 oz. of blood. The heart

FIG. 3.



A represents the same as in Fig. 1. B represents the second rent with the second invagination passing through it.

showed some hypertrophy of the left ventricle but all the valves were perfectly healthy. There was a complete rupture of the aorta in a slightly oblique direction about ¾ in. above the aortic valves. The pericardium covering the ascending aorta had been forced away from the outer coat of the vessel as far as the origin of the innominate artery and was distended with recent blood-clot forming the wall of a false aneurysm. The ascending portion of the aorta was

Digitized by Google

invaginated into the transverse portion as far as the commencement of the descending portion. This, however, was not a simple invagination as the intima of the penetrating portion looked inwards, and not outwards, towards the intima of the receiving portion. At first sight it was not apparent how this had been brought about and not till the invagination had been reduced was it discovered that

FIG. 4.

A and B represent the same as in Fig. 3.

there was yet another invagination. It was then seen that the condition had been produced thus. The ruptured end of the aorta had been turned inwards and passed through a rent in the arterial coats just below the origin of the innominate artery, as shown in Fig. 1, thus occluding the passage for the blood into the transverse aorta. A second invagination had then taken place, the ruptured end again

FIG. 5.

Showing the appearance of the invagination.

turning in and passing through a second rent in the arterial walls into the lumen of the transverse aorta. Fig. 2 shows this second invagination just commencing, and in Fig. 3 it is seen at a further stage after passing through the second rent. Fig. 4 showing it forced further through in the condition in which it was found. In these figures the first rent is marked A and the second rent B. A way for the blood to pass from the cavity of the false aneurysm into the aorta was thus restored. These figures are very diagrammatic and it has not been attempted to represent in them the fact that the different coats of the vessel were not all torn through at exactly the same place. In the case of the rent marked B the opening was markedly valvular, the intima being ruptured ½ in. further down the vessel than the adventitia. Fig. 5, which is reproduced from a photograph, gives a good idea of the appearance of the invagination. The transverse aorta is slit up to expose the invaginated ascending portion and the left ventricle and the commencement of the aorta are also cut open. There is a blow-pipe (1) passed through the lumen of the invaginated portion showing the course the blood took from the aneurysmal cavity into the descending aorta. A needle (2) is passed through the first rent (A) through which the primary invagination took place and a needle (3) is passed through the second rent (B) through which the second invagination had taken place, a third needle (4) is passed from the cavity of the aneurysm into the commencement of the innominate artery which was torn off from the aorta, and there is a needle (5) placed in the pericardial cavity lying in front of the parietal layer and partly concealed by the visceral layer of pericardium which had been forced away from the outer coat of the aorta.

Remarks by Dr. ASHWIN.—The above case of rupture of the aorta is, I think, interesting, not only on account of the rarity of the accident but also because the distal portion was invaginated twice through two distinct rents in the coats of the artery in such a manner as to restore the lumen of the vessel so that the circulation was maintained and life prolonged for five and a half hours after the occurrence of the rupture. As regards the cause of the rupture I fear I can make no suggestion. The patient does not appear to have been making any violent exertion at the time of its occurrence and the aorta was remarkably healthy for a man of his age, there being only two small patches of atheroma, one of which is marked 6 in Fig. 5. The brain was perfectly normal. I am indebted to Dr. Petch for permission to publish the case and to my senior colleague, Dr. G. W. Gostling, for his assistance and valuable suggestions at the post-mortem examination.

Medical Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF ANATOMY AND PHYSIOLOGY.

Irregular Phrenic Nerve.—Muscular Fibres of the Œsophagus.—Muscular Fibres of the Stomach.—Dislocation of Crystalline Lenses.

A MEETING of this section was held on June 3rd, Dr. D. J. COFFEY, the President, being in the chair.

Dr. J. BARTON read a short note on an Irregular Phrenic Nerve which came off from the fourth cervical and ran for one and a half inches in the trunk formed by the fifth and sixth nerves, getting a branch from the fifth. It then passed downwards and inwards in contact with the posterior surface of the sterno-mastoid, crossed the subclavian vein opposite the insertion of the scalenus anticus, and entered the thorax in front of the internal mammary artery and right innominate vein and then passed down by the vena cava and pericardium as usual. He also referred to the frequency with which the phrenic nerve passed behind instead of in front of the internal mammary artery.—Professor BIRMINGHAM suggested that the phrenic had perhaps associated itself with the nerve to the subclavius for some distance in this specimen and exhibited a specimen illustrating the Course of the Left Phrenic Nerve in the Upper Part of the Thorax, which he thought showed the true position of the nerve at a part of its course which is generally neglected in the usual descriptions.

Professor BIRMINGHAM read a paper on the Muscular Fibres of the Œsophagus in which he pointed out (supporting his views by several specimens) that the usual description which made the longitudinal fibres of the œsophagus divide above into three bands, two of which were said to be

Digitized by Google

attached to the inferior constrictor and a third to the ridge of the cricoid, was inaccurate. He showed that these longitudinal fibres formed two chief bands above, which were first placed laterally and then wound round to the front, where meeting they passed into a tendinous band one-fourth of an inch wide, and this was attached to the top of the back of the cricoid at the upper end of its ridge. He also explained in detail the arrangement of the muscular fibres at the upper end of the tube and showed the part played by the inferior constrictor in uniting the pharynx and œsophagus.

Professor BIRMINGHAM also read a communication on the Arrangement of the Muscular Fibres of the Stomach. He agreed with the usual description of the longitudinal fibres. With the description of the circular fibres found in all our text-books he could not agree. These fibres were described as forming rings round the organ from the fundus to the pylorus. This is inaccurate. The fibres which form rings round the fundus and the adjacent part of the stomach to the left of the œsophagus belong to the deepest or oblique layer of the muscular coat. The detailed arrangement of the oblique fibres was given and the connexion of the three layers with the fibres of the œsophagus and the points brought out were illustrated by dissections of stomachs in which the muscular fibres were well developed.—Professor FRASER referred to the tendency exhibited by different observers to work out various patterns in the arrangement of the muscular fibres of organs. He remembered when Dr. Pettigrew showed figure of 8 arrangements first in the heart and then tried to make them out in the other viscera. He had not made special dissections of the fibres in the stomach, but he had, he thought, seen the three longitudinal bands described at the upper end of the œsophagus.—Professor BIRMINGHAM, in reply, said that he had made a considerable number of dissections of the œsophagus with the greatest care and in none of them had he found three bands present.

Dr. R. J. MONTGOMERY exhibited a child, aged about eleven years, in whom both Crystalline Lenses were Dislocated Upwards and Outwards. The displaced structures and the amount of their displacement were easily seen with the aid of a simple lens. The only noticeable effect on the vision of the patient was an inability to see small objects clearly.

Reviews and Notices of Books.

A Manual of Surgery for Students and Practitioners. By WILLIAM ROSE, M.B., B.S. Lond., F.R.C.S. Eng., Professor of Clinical Surgery in King's College, London, and Senior Surgeon to King's College Hospital, and ALBERT CARLESS, M.S. Lond., F.R.C.S. Eng., Senior Assistant Surgeon to King's College Hospital, and Teacher of Operative Surgery in King's College, London. London: Baillière, Tindall, and Cox. Demy 8vo, pp. 1162. 1898. Price 21s. net.

FOR a long time it has been generally recognised that a text-book of surgery for the average student has been greatly needed. The almost classical work of Erichsen is still, as it has been since its first appearance, the most trustworthy guide to the art and science of surgery, but, as every teacher of surgery knows, it is impossible to get the average student to read so big a book, and as a rule only those who aim at the degrees of the University of London are willing to peruse it to the end. The other text-book in common use is Walsham's, and though it is a wonderful example of a large amount of information compressed into a small space, yet it is hardly sufficient for many of the examinations in surgery. So an obvious need exists for a book on surgery for those students who take the examinations held by the Conjoint Board in England and other examinations of an equal standard. It is no easy matter to include all that such a text-book should contain and yet not to introduce details which will serve only to overburden the memory of the student. This real want has, in very great part at least, been supplied by the work which lies before us.

The first chapter is devoted to Inflammation, and this difficult subject is presented very clearly; a brief though adequate account is given of the importance of micro-organisms as causes of inflammation, and the present theories of immunity are described. To only one statement in this chapter would we take exception; the offensiveness of the motions in pyrexia is ascribed to the loss of the antiseptic power of the bile; it is now generally recognised that the bile has practically no antiseptic property at all. The chapter on Suppuration and Abscess is good, and especially useful is a table on the methods of opening abscesses in various parts of the body, such as mammary and retropharyngeal abscesses. Sepsis and Infection are dealt with fully and the account is quite up to date; the less important diseases and conditions are printed in a type smaller than the rest of the subject. By this plan which has been adopted throughout the volume much space has been gained. In the description of the treatment of wounds the authors express themselves strongly in favour of the antiseptic as opposed to the aseptic method, but they acknowledge that the aseptic method has been employed with much success, though as it requires many elaborate precautions they do not consider it well suited to a large city hospital. We are glad to see that much stress is laid on the importance of early massage in the treatment of fractures near joints. If this practice were more generally adopted it would do much to prevent the stiffness which so often proves a troublesome sequela in these cases. On page 533 we are told that tuberculous disease of the phalanges was "formerly described under the meaningless title of 'spina ventosa.'" We should be interested to learn on what authority this statement is made, as we were under the impression that the term "spina ventosa" was applied to sarcomata of bone which had undergone cystic degeneration. On the whole, it would have been better to have omitted the term from a book intended chiefly for students; it is better left in oblivion.

The chapter devoted to Abdominal Surgery is very good indeed and fully represents the current views. The sections devoted to the Nose and the Ear have been looked through by Dr. St. Clair Thomson and Dr. Silk is similarly responsible for the contents of the chapter on Anæsthetics. In all there are 392 illustrations, many of which are familiar, as they have already appeared in other works, and for the most part their source has been acknowledged; but we find no small number which have certainly been used on a previous occasion and yet no mention of their having been borrowed is made. Even taking these in account, however, there are numerous excellent illustrations which have been specially prepared for this volume.

The more we examine the book the more we are inclined to pronounce it to be the best manual of surgery for all students who do not aim at the highest examinations. The descriptions are clear, the accounts of disease are concise yet not cramped, and the style is easy. We venture to predict for this work a wide and prolonged success.

Text-book of Nervous Diseases. By CHARLES L. DANA, A.M., M.D. Fourth edition, revised and enlarged. London: J. & A. Churchill. 1898.

A FEW years ago, in noticing the second edition of this work, we ventured to predict that it was likely to become a favourite text-book in America. The appearance of a fourth edition would seem to verify our prediction and it may be said without hesitation that this new edition, in type, in general appearance, and in matter, marks a great advance on its predecessors. There are about 100 pages more than in the second edition and for most of these the fresh considerations rendered necessary by the recent advances in the anatomy of the nervous system are mainly responsible.

Digitized by Google

But the page is larger, the type is more distinct, the illustrations are more numerous and better executed, and, in short, the *tout ensemble* is more worthy of the subject. Although the old division into three parts is dispensed with the chapters fall very much into line with those of the former editions, but each chapter has undergone thorough revision, and in reference to its particular subject has been brought well up to date. In short, the book is a most excellent "compendium for the use of students and practitioners of medicine," but it is redeemed from being merely this by the wide clinical and pathological experience of the author, which is evident on almost every page. Dr. Dana is to be cordially congratulated on the appearance of what is, in many respects, a new book and one which will be of no little use to those whose busy lives prevent them from having recourse to larger and more comprehensive treatises.

Convergent Strabismus and its Treatment: an Essay. By EDWIN HOLTHOUSE, M.A. Cantab., F.R.C.S. Eng., Surgeon to the Western Ophthalmic Hospital. London: J. & A. Churchill. 1897. Pp. 177. Price 6*s*.

IN 1854 a course of six lectures on the Pathology of Strabismus and its Treatment by Operation was delivered at the Westminster Hospital by Mr. Carsten Holthouse, the then assistant surgeon to the hospital and lecturer on anatomy in the medical school, and we now welcome an essay on the same subject by Mr. Edwin Holthouse, the son of the preceding author. Much space was taken up in the former course of lectures in detailing the anatomy and physiology of the ocular muscles, and various points in regard to the indications for the performance of an operation and the modes of operating, which at that time occupied much attention but upon which there is now a very general consensus of opinion, were considered. The present volume is written from a higher and better standpoint and is the outcome of a large amount of clinical experience and of careful thought over the data which have been obtained. The constancy with which convergent strabismus is associated with hypermetropia is well brought out, for amongst 144 cases no less than 142 were hypermetropic and only 2 myopic. Of the 142 cases 7 were periodic and 123 constant, and of these 123 were unilateral and 12 alternating.

Mr. Holthouse carefully compared the refraction of each of the eyes of 120 patients and obtained interesting results, for he found amongst the fixing eyes that 40 per cent. were affected with simple hypermetropia and 60 per cent. with compound hypermetropic astigmatism, whilst amongst the deviating eyes 25 per cent. had simple hypermetropia, 72·5 per cent. were affected with compound hypermetropic astigmatism, 0·83 per cent. with simple hypermetropic astigmatism, and 1·66 per cent. with mixed astigmatism, showing that whilst ametropia was present in all the fixing eyes its more complex forms were found in a higher ratio among the deviating ones. Nevertheless that this difference does not afford a complete explanation of the occurrence of squint is sufficiently demonstrated by the circumstance that anisometropia is common amongst those hypermetropes who do not squint, whilst it is not invariably present in those who do and, further, it appears from Mr. Holthouse's observations that in no less than one-seventh of the whole number some other factor than mere inequality of refraction must be sought for as the proximate cause of the squint. This is supported by the fact that in nearly one-fourth of the cases the degree of hypermetropia did not in the fixing eye exceed 2·5 diopters—a degree requiring no extraordinary nervo-muscular effort to overcome.

Mr. Holthouse discusses at some length the question of the impairment of vision in the squinting eye, whether it is a cause or a consequence. Some maintain that in cases of squint more or less perfect binocular vision was originally present, but that as a result of diplopia arising from some defect, to escape the consequent annoyance the images formed on the retina of the deviating eye are ignored or suppressed, such suppression leading in the end to actual loss of the visual power. Others, again, hold that the defective vision of the squinting eye is not acquired but is congenital and that it constitutes a chief factor in the production of squint. And there are still others, with whom we should feel inclined to agree, who combine the two views above mentioned and who believe that a congenital or acquired defect in one eye places that eye at a disadvantage to the other and leads to suppression of the images it receives and further impairment of vision by disuse.

The results obtained by Mr. Holthouse from the systematic employment of appropriate glasses are of considerable interest, for he has found that complete cure, independently of the further use of glasses, occurs in about 13 per cent. of the cases, a number sufficiently high to make it worthy of a trial in all, more especially as in an additional 17 per cent. the eyes became straight during the time that the glasses were actually worn, whilst in 62 per cent. of all the cases improvement was noted. In a certain number of cases tenotomy must be performed to effect a cure, and he advocates single tenotomy in the first instance, and if this be not successful an "advancement" of the external rectus of the deviating eye.

Genito-urinary Surgery and Venereal Diseases. By J. WILLIAM WHITE, M.D., Professor of Clinical Surgery, University of Pennsylvania, and EDWARD MARTIN, M.D., Clinical Professor of Genito-urinary Diseases, University of Pennsylvania. Illustrated with 243 Engravings and 7 Coloured Plates. Philadelphia: J. B. Lippincott Company. Pp. xix. and 1061. 1897.

WE may state at once that this volume is in every way worthy of the two distinguished surgeons whose names appear on the title paper. It is comprehensive in its scope clear in its descriptions, and judicious in the treatment, and though we cannot go so far as to say that we agree with everything the book contains, yet there is wonderfully little in the whole volume to which we can take exception. The book is well printed, and the authors are especially to be congratulated on the excellence of the illustrations; many of these are reproductions of photographs and in nearly every case the points which it was intended to show have been well brought out. A large number of the illustrations in the section on Syphilis come from the collection of Dr. G. H. Fox. The venereal diseases—gonorrhœa, chancroid, and syphilis—form the first section. In the description of venereal warts the authors employ the term "condyloma" without any qualifying word; this is liable to cause some confusion in the mind of the student when he finds that this name is also given to a very characteristic syphilitic lesion. It is certainly better to limit the application of the word to the syphilitic condition. We would specially commend the section dealing with the treatment of Stricture of the Urethra; it is thoroughly up to date. A very useful chapter is that devoted to the care of urethral instruments. The authors consider that a 25 per cent. solution of boro-glyceride is a very good lubricant for catheters as it is antiseptic and very slightly irritating, though they think that oils, especially fluid albolene and castor oil, are really the best lubricants. For the sterilisation of gum elastic catheters which are so injuriously affected by boiling, the use of the vapour of formol, as introduced by Janet and Guyon, is advised; the only objection to the method is that the process requires that the instruments should be subjected to the vapour for 24 hours. The article on Syphilis

Digitized by Google

excellent; it occupies nearly 250 pages and contains 59 illustrations.

The authors distinguish between floating and moveable kidney. They define the floating kidney as one possessing a mesonephron and state that a moveable kidney is situated entirely behind the peritoneum and moves because it is unsupported. The distinction is of very little practical importance.

In the account of the etiology of hydronephrosis it should have been pointed out that sudden complete blocking of a ureter produces not a hydronephrosis, but atrophy of the kidney, and that the obstruction must have been incomplete or intermittent if it leads to dilatation of the kidney. It might have been mentioned in the account of the orchitis which may complicate mumps that the orchitis is more frequently met with when the patient is an adult than when he is a child; possibly the functional capability of the organ predisposes it to inflammation. The index is exceptionally good.

Burdett's Hospitals and Charities, 1898: the Year-book of Philanthropy and Hospital Annual. London: The Scientific Press, Limited. Price 5*s*.

SIR HENRY BURDETT'S valuable handbook of information on everything which concerns hospital finance and other charitable subjects presents in this its ninth yearly issue some new features, in that two chapters of the preliminary matter are taken up with the events of last year as affecting the stream of charity and with the Prince of Wales's Hospital Fund. Sir Henry Burdett is by no means in agreement with those who said that the Fund would prove a failure. It is true that the sum desired was an annual income of £100,000 and that although the whole sum received was £227,584 the amount of annual subscription was only in round numbers £22,000. But Sir Henry Burdett estimates that in all 1,100,000 people subscribed something. Purchasers of hospital stamps he considers amounted to nearly 400,000. The *Daily Telegraph's* fund produced £25,000 in shillings alone, which accounts for another 500,000 subscribers, and *Lloyd's Weekly News* by a penny subscription collected £2618, probably representing 250,000 contributors. So that at a moderate estimate Sir Henry Burdett thinks that we may fairly say that at least 1,100,000 persons subscribed. It seems to us that that is a fair supposition; in fact, very possibly the figures are too low. Sir Henry Burdett goes on to say that of this number it may reasonably be expected that 400,000 will continue their subscriptions; on this point, however, we are not so sure as Sir Henry Burdett. It remains to be seen whether many of the subscribers will not drop off in forthcoming years. The year 1897 was, however, one of unexampled prosperity for the hospitals in general, for the total income of 93 metropolitan hospitals for the year was £998,774, while in 1896 it was £787,384, although in 1895 it amounted to £932,543. Another point to which Sir Henry Burdett draws special attention is the necessity of every general hospital providing an annexe composed of paying wards. "Fitzroy House," he says, "is a pay hospital pure and simple, and it would be to the advantage of everybody for a bridge in the shape of pay wards to be built to connect it with the great general hospitals, so that all classes of the community might be adequately provided for in the time of sickness." Patients, of course, could be attended if they wished by their own doctors. In Sir Henry Burdett's opinion the "attempt to set up a hospital for middle-class patients as a separate institution must result in ultimate disappointment and pecuniary loss."

The question of paying hospital patients opens up far too many and important difficulties to be dealt with in the compass of a review, so we shall merely say here that we cannot agree with Sir Henry Burdett's ideas. Apart from these points the statistical and other information as to the various hospitals and charities is as full and useful as in any of the former volumes.

LIBRARY TABLE.

Synopsis of the British Pharmacopœia, 1898. By H. WIPPELL GADD. London: Baillière, Tindall and Cox. Bristol and Exeter: Evans, Gadd and Co. 1898. Pp. 183.—The merit of this compilation is sufficiently shown by the fact that it is now in its second edition, the first having been quickly exhausted. The usual enumerations of additions and omissions are followed by lists of the principal alterations (chiefly in strength), alterations of names, and tables of the various alcoholic solutions which will now replace the rectified spirit and proof spirit of previous Pharmacopœias. The greater part of the book—about 130 pages—consists of a Complete Table of the Chemicals, Drugs, and Preparations of the new Pharmacopœia, with their Characters, Doses, and other particulars. This table, which is in five columns and is made very compact, begins with Acaciæ gummi and ends with Zingiber.

Comfort and Cleanliness. By Mrs. C. M. BUCKTON. London: Longmans, Green and Co. 1898. Price 2*s*.—The sub-title of this little book is "The Servant and Mistress Question," a subject which no one will deny is an important one. We can conscientiously praise Mrs. Buckton's instructions as to how to keep a house clean. The difficulty for most housekeepers is, however, not so much how to do things but to find servants who will do them. Mrs. Buckton gives very full and clear instructions as to how to clean and keep in order a "kitchener." A clean house means a healthy house and towards this desirable end we recommend a study of this book.

Handbook of Obstetric Nursing. By F. W. HAULTAIN, M.D. Edin., and J. H. FERGUSON. Edinburgh and London: Young J. Pentland. Third edition. 1898.—The fact of this book having reached a third edition may be taken as a proof that it supplies a want. The present edition has been carefully revised and brought up to date, an account of an incubator having been added. The absolute importance of cleanliness and antiseptics is made a special point and we are glad to see the stress laid upon the danger of producing cystitis by a dirty catheter or by carrying infectious matter from the vulva or vagina into the bladder. Directions are given how to avoid this calamity (pp. 222–224). The book is clearly written and very useful.

Atlas und Grundriss der Traumatischen Fracturen und Luxationen. Von Professor Dr. H. HELFERICH in Greifswald. Mit 68 Tafeln und 126 Figuren im Text von Maler B. KEILITZ. Dritte gänzlich neubearbeitete Auflage. (*Atlas of, and Introduction to, Fractures and Dislocations.* By Professor Dr. H. HELFERICH of Greifswald. With 68 Plates and 126 Figures in the Text by B. KEILITZ. Third entirely revised edition.) München: Verlag von J. F. Lehmann. 1897. Preis Mark 12 (12*s*.).—All who are acquainted with German medicine and surgery know the very useful volumes of this series issued by Lehmann of Munich. One of the best of them is the work before us; the first edition was good, but this third edition is in many ways a great improvement. The book has been almost rewritten and the plates are new. The author tells us in his preface that his aim has been to make the book of use to those in practice, and we think that no one who can read German could have a more useful book than this to consult on the question of fractures and dislocations. The engravings in the text are chiefly concerned with methods of treatment, but the plates have to do with the anatomy of the lesions dealt with. The plates are most successfully lithographed in colours; we have never seen any which represented in a better manner the structures which they are intended to portray.

THE LANCET.

LONDON: SATURDAY, JULY 9, 1898.

THE multiplication of universities is a subject upon which much may be said and with regard to which a great variety of opinion exists. But we are disposed to think that the citizens of Birmingham, ably led by a distinguished statesman, are acting wisely in resolving to found a university for Birmingham and the Midlands. The country owes much to the stimulus given to national education, elementary and secondary, by Birmingham men, and in their own city both primary and secondary education have been carried to a perfection which will bear favourable comparison with the state of the same in any similar community. It is altogether natural that men who have been so successful in the promotion of elementary, secondary, and technical education should wish to crown their efforts by establishing a veritable university which shall supply to the city and the surrounding Midland district, with an estimated population of 2,000,000, the undefinable but unmistakeable advantage of a university in which all faculties shall be treated with equal favour and, above all, in which care shall be taken that in all faculties shall be required that preliminary "general culture of mind which is the best aid to professional and scientific study."

It would be a poor compliment to the shrewd men of Birmingham to think that they are under any delusion as to the conditions under which alone a Birmingham university will be able to claim the respect paid in England to her older universities, or that they imagine that by merely raising two or three hundred thousand pounds for the creation of a so-called University their institution will forthwith command either the esteem of the public or the respect of sister universities. If we thought that their estimate of the meaning of a university was thus shallow we should offer to the movement our most decided opposition. But the speeches made at the meeting on July 1st (brief notes of which will be found in another column of our present issue), not only by Birmingham men like its LORD MAYOR, Mr. CHAMBERLAIN, Mr. G. H. KENRICK, and Professor TILDEN, but by independent observers such as the Bishop of HEREFORD, are enough to refute such a fear. And, as we have already suggested, it is also refuted by the extremely good educational work which has already been done in Birmingham and which has led naturally and logically to the present demand. It is impossible to deny that the countries in which universities abound have an advantage over others in which they are few and far between. The case of Scotland, quoted by Mr. CHAMBERLAIN, is very striking. That of Germany is equally so with its 21 universities, having an annual income of £1,250,000, three-fourths of which are contributed by the State. Scotland has done well for her own people by her universities. The humblest of her population have strained to send their sons to them for a training which has fitted them to fill posts of honour in the services and in the professions of the empire, as well as in the British and Colonial Parliaments. The United States carry the multiplication of universities to an excess; but three of their universities have an income of £400,000. Germany threatens by her technical schools and universities to lead not only the intellect, but the commerce, of the world. It would be folly on the part of England not to take such lessons to heart and resolve therefore to spend her ample wealth in refining and perfecting the education of her people. Her material is not inferior to that of the nations which we have named, and it will only be by stinting it in nourishment—i.e., by starving education in its highest and best forms—that she will fall behind in the race of nations.

Two objections may be raised to the creation of a new university in Birmingham. One is that it may fail by the competition of the ancient universities. No doubt these institutions have the charm of a great past and are evincing evidence of fitness for a great future. They will long continue to attract the best thinkers and the best teachers and, perhaps the best students. But there is plenty of proof that there is work for other and more accessible universities whose own fault it will be if they do not give a good account of their opportunities by making a material contribution to the mental and moral cultivation of the people in whose midst they are placed. The other objection is from a medical standpoint — that a new university implies an addition to the already too large number of qualifying medical bodies. This is a real and a strong objection. But it can scarcely of itself be held to justify opposition to a university if on other grounds there is a just claim for it. The addition of one more qualifying body to the present ones cannot make much difference to the system, and we here desire to throw out a suggestion. If the University College of Bristol were included in the scheme of the new Midland University every medical school in England would be affiliated to a university—assuming, as we suppose we may, that the Government intends to pass the Bill for the reconstitution of London University. The movement in favour of a new university may also have the effect of directing public attention to the fact that no authority rests with the General Medical Council or any other body to ascertain whether the knowledge required for obtaining university degrees in medicine is in any way superior to that required for the ordinary qualifications to practise. Such a distinction is assumed by the public. University authorities would blush to admit that the public is wrong in that assumption. If universities are to be multiplied some guarantee must be given that standards of graduation shall be kept high.

THE withdrawal by Mr. CHAPLIN of his amendments to a private Water Bill—which amendments were, if accepted by the House of Commons, to have been made general to all Water Bills before the House during this session—is a severe blow to public health interests in this country. It is true that the objection raised was professedly to the introduction of the new clauses in a few private

Digitized by Google

Bills instead of their embodiment in a general Act; but it was perfectly obvious to those present at the debate that the real opposition was due to the fear that the clauses might act injuriously to the pecuniary interests of water purveyors. Indeed, it may be assumed that if the President of the Local Government Board should introduce a general Bill dealing with this subject next session, the "water-interests," which are powerful in the House of Commons, will find that new objections have arisen which will demand the rejection of a general piece of legislation just as the one objection raised this session demanded the withdrawal of the proposals submitted. It is this aspect of the question which is so serious. The clauses, it is true, were not rejected; but the opposition to them had been so well worked up that if they had been pressed to a division the Government, in the person of Mr. CHAPLIN, would have met with a substantial defeat. Hence the clauses were withdrawn.

The essence of the clauses in question was briefly as follows. They enabled a medical officer of health or other person sanctioned by an authority whose district is supplied by a company to take samples of water from any point within the company's works on giving proper notice in advance; and they gave similar powers to any consumer of the water provided he had obtained an order from a justice of the peace authorising him so to do. And, further, they gave powers to water companies to enter upon any lands, such as gathering grounds from which their water was derived, and to take samples of water at various points where such water might be fouled. In this way some provision was made by which authorities and individuals who were compelled to take, use, and pay for a certain water-supply might protect themselves against an unwholesome supply, and might obtain some assurance as to the quality of the water which they had no alternative but to use for domestic purposes. And, on the other hand, provision was made by which water authorities deriving their supply from sources beyond their immediate control might have access to all those sources so as to secure the removal of obvious sources of pollution. The whole of the proposals were in the interests of public health, but incidentally they conferred a great boon both on purveyors of water and on water consumers. The purveyors and their shareholders were too strong at the moment and as a consequence the public must continue to submit to be without protection against the conditions of fouling of public water-services that have within recent years led to such disastrous consequences.

For the present the main question is to determine how best to secure the introduction and the passing of a general Bill next session. In this matter it is important to remember how strong the water interests are in Parliament and how necessary it will be in consequence to support the Government in any action which they may take. For this purpose all who are interested in the protection of the public from the risks attendant upon polluted water-supplies, and all who are interested in securing the purity of the sources of water in which they have a pecuniary interest should lose no time in maturing an organisation which will strengthen the Government and ensure them the support of Parliament in their endeavour to meet the difficulty with which they have unexpectedly found themselves confronted. Medical officers of health will have special influence in setting such organisations in motion, in preparing petitions to the President of the Local Government Board urging the Government to proceed in the matter at the earliest possible opportunity, and in inducing local authorities to ask that deputations may be received at Whitehall with a view of setting out the considerations involved. And in a similar way societies dealing directly or indirectly with questions bearing upon public health may usefully pass resolutions in the same sense and transmit them to the Local Government Board. Unless something of this sort is done the subject may not after all be dealt with in a Government Bill and the Government majority may feel free to act and to vote under the influence of considerations which will be adverse to public health interests.

TWICE convicted of the crime of felony WILLIAM MAUNSELL COLLINS was sentenced at the Central Criminal Court, on July 2nd, to seven years' penal servitude. As Mr. Justice GRANTHAM remarked the prisoner had experienced a chequered career. Possessed of more than average ability he appears to have been unusually favoured by fortune in the earlier years of his professional life. At one time surgeon to the Royal Horse Guards he afterwards engaged in private practice. Some few years since he forged the signature of his patient and friend and for the offence was indicted and convicted on pleading guilty at the Old Bailey. His escape from punishment was at the time the theme of general comment and the serious nature of the crime did not require the observation of Mr. Justice GRANTHAM, that "had he been sentenced he would probably not have had the opportunity of standing in the dock on the present charge," to show that the punishment commensurate with his guilt would have been of no slight magnitude. He was struck off the Medical Register on being convicted of felony, so that at the time of his attendance on the late Mrs. UZIELLI he had no legal status as a medical man.

The evidence in the recent case proved that Mrs. UZIELLI had reason to believe she was *enceinte* and further that she was desirous of being freed from that condition. She had approached her usual medical attendant with a request to aid her to that end. If she did not visit COLLINS for the purpose of engaging his services for an unlawful act, why did she keep from her husband, who is said to have enjoyed her confidence, the fact that she had consulted him at all? and why did she approach COLLINS'S house more or less clandestinely? The clinical history of the crime was singularly complete in circumstantial detail. COLLINS in his evidence before the Coroner averred that Mrs. UZIELLI had a displacement of the womb which he attempted to rectify, but the post-mortem examination disclosed no such displacement at the time of the decease and indicated, moreover, that it had not existed previously—a singular negation of COLLINS'S alleged knowledge and skill if he was an innocent man. Again, whatever the temperament of Mrs. UZIELLI as tending to exaggeration of her symptoms, there was the damning reply that within a few hours of COLLINS'S statement that the case was progressing satisfactorily Dr. STIVENS diagnosed with

Digitized by Google

certainty septic peritonitis and foretold a probably fatal issue. On the next day Mrs. UZIELLI died, when Dr. STIVENS refused to certify the cause of death and gave notice to the coroner. We endorse every word spoken by Mr. Justice GRANTHAM as to Dr. STIVENS'S paramount duty under such circumstances. Mr. BOND, who made the necropsy, found that there had been a recent pregnancy. He also found a punctured wound made by some blunt instrument—a wound that, in his opinion, could not have been made with a curette employed, as COLLINS stated, to remove some retained membrane when he became aware that Mrs. UZIELLI had aborted. It may be remembered that the same authority had in another case in which COLLINS was concerned admitted that the laceration discovered in the wound might have been made with a curette—a complete reply to any suggestion that Mr. BOND was biased, had such reply been required. It was not required. Mr. BOND'S reputation and position as standing adviser to the Treasury were sufficient guarantee of his single-mindedness and trustworthiness. The proximate cause of Mrs. UZIELLI'S death was thrombosis of the pulmonary artery, the last link in the chain of morbid events caused by infection of the uterine wound. That there was evidence of the effects of a partial pelvic inflammation long before subsided, in our opinion, was of no pathological moment. It might predispose to a recurrent attack of peritonitis and it might predispose to miscarriage, but what of the punctured septic wound? Naturally Mr. BOND could not do more than approximately fix the date of infliction of the wound, and counsel for the defence wisely did no more than suggest that some other person might have performed the criminal act prior to or after COLLINS'S introduction to Mrs. UZIELLI. Had such been the case would COLLINS not have recognised the fact and acted accordingly? Besides, there was no single fact to prove that Mrs. UZIELLI had submitted herself to operative interference by any other person than the prisoner. It was idle to allege that COLLINS'S failure to procure medical evidence in his favour was due to his impecuniosity. As Mr. Justice GRANTHAM remarked, the medical profession is a large-hearted one. Its generosity, we may say, would have been ample to have extended a helping hand even to a man whose name had been removed from the Register of honourable practitioners.

We have nothing but praise for the matter and manner of the summing up by the learned judge. It was strong but it was just. The evidence led irresistibly to a record of guilt, but why the jury strongly recommended the convict to mercy we do not understand. Probably this recommendation had its weight with the judge or he would have exceeded the merciful sentence of seven years' penal servitude. We have frequently drawn attention to the heinousness of the crime of abortion and have expressed the opinion that its wickedness is grossly exaggerated when committed by a person who is fully cognisant of the danger to the life of the woman. Constructive murder it undoubtedly is and legally it is murder, and the fact that the culprit has every reason to hope that the victim will not die accounts only illogically for the reluctance of juries to convict on the capital charge. We were glad to read the pronouncement of Mr. Justice GRANTHAM that the woman who submits herself to an unlawful operation is guilty of a felony just as much as the agent whom she employs; nor should it be forgotten that any person aiding or abetting is also answerable to the law. The crime of abortion, there is reason to believe, is rife in all classes of society. Though there is little to be said in extenuation of the guilt in the case of single women whose character and livelihood might be jeopardised by the fact of maternity, there is absolutely nothing to lessen the offence of those who, whilst indulging in marital privileges, are so lost to all sense of shame that merely for the sake of fashionable engagements they will sacrifice their honour and their lives. They bring disgrace on the hallowed names of wife and mother. Such a canker in our social life requires that condign punishment should be inflicted on criminal abortionists, whether they be principals or abettors. We sincerely trust that the authorities will vigorously endeavour to put down a crime "despised by men and forbidden by GOD."

Annotations.

"Ne quid nimis."

THE ROYAL ARMY MEDICAL CORPS.

THE Royal Warrant constituting the new Royal Army Medical Corps, which Mr. Powell Williams stated in the House of Commons on June 27th had been approved by Her Majesty and would be published in the Army Orders for this month, has now appeared and a copy of it will be found in the present number of THE LANCET (*vide* p. 98). The Army Medical Service will henceforth take its place side by side with the other scientific branches of Her Majesty's Army—namely, the Royal Engineers and Royal Artillery—a position which we have always contended it should properly and legitimately occupy—and purely military titles have, in accordance with Lord Lansdowne's announcement, been assigned to medical officers up to the rank of Colonel, so that there can no longer be any doubt about their exact army rank. Surgeon-Major-Generals will, however, be styled Surgeon-Generals with the rank of Major-General. The warrant, as will be seen, deals simply with the constitution of the new Royal Army Medical Corps. It only remains for us to congratulate the medical officers and the profession generally on the important change which has taken place. We think that the Minister for War and the present Government are also to be congratulated on the step which they have taken. There is no reason why the Royal Army Medical Corps should not now become a deservedly popular service and attract a number of well-trained candidates from our universities and medical schools. Lord Lansdowne has done all he could to secure medical officers an assured rank and honourable position in the Army worthy of the profession to which they belong, and his efforts in this respect deserve to be ungrudgingly and gratefully recognised. We hope that they may prove successful in inducing a large and good class of men to compete for places in the Royal Army Medical Corps at the next and succeeding examinations.

MEDICAL DEGREES AND CRIME.

WE have dealt elsewhere with the case of Mrs. Uzielli and all its unpleasant lights on the state of social morality in some classes of society. The medical profession has some right to complain of the state of the law on this subject. It

Digitized by Google

had long since relieved itself of the responsibility of association with Dr. Collins. The General Medical Council, which in such matters represents the profession, some years ago for the offence of forgery—for which by some strange failure of justice no punishment was awarded—erased Dr. Collins's name from the Register. And he so ceased to be a qualified medical man. But unfortunately he did not cease to be a graduate of his university, the Queen's University, Ireland. To do his university justice it is questionable whether it has the power at present to remove Dr. Collins's name from its list of graduates — a power which nearly every medical corporation has. Surely this is a monstrous state of things. *Noblesse oblige.* Certainly universities should not be behind corporations in preserving the purity of their roll and in giving guarantees to the public that their graduates are men of character. We have no wish to strike a man when he is down, but the public interest here is terribly at stake and so is the fame of universities. It would be a questionable modesty which should allow any false sentiment to prevent Dr. Collins's case being used for the correction of this great defect in university discipline.

THE PUBLIC PARKS.

Now that warm weather has set in and the ground has become fairly dry the London parks are once more tenanted by their usual inhabitants. We do not refer to children who play or to citizens of the humbler or the richer classes who take their sober pleasure therein, but to the collection of tramps who seem past tramping, filthy outcasts of both sexes, who spend the day singly or in groups asleep on the grass, occasionally sitting up to converse, to arrange their horrible rags, and otherwise occupy the time until they are turned out to wander in the streets or lie upon the pavement until the gates are opened again in the morning. The worst specimens of these, the absolutely homeless, as distinct from slum-dwellers who crawl up to St. James's Park as a rule from the smaller streets in Westminster, are, perhaps, most in evidence at the north-east corner of Hyde Park, near the Marble Arch, and must form a very unpleasant subject of contemplation to dwellers on the other side of the Bayswater-road, who, indeed, at times protest in the newspapers. We do not dwell upon the subject from the point of view of the wealthier inhabitants of West London, nor do we go so far as to say that each of the ragged objects alluded to is a certain centre of infection, whatever they may be capable of becoming, and we admit that the vermin which infest them are not likely to leave them and roam in the grass, at least not of their own free will, but we do say that a large portion of the finest park in London is practically rendered useless for the object for which, in our opinion, it should be maintained—namely, the recreation of the citizens at large and of their children in particular. The distinguished military gentlemen whose names are in public lists as its custodians (we do not refer to H.R.H. the Duke of Cambridge, whose post of Ranger is honorary) may not care, or may say that the task of keeping out or moving on the slumbering ragamuffins is beyond their powers. As to the first of these objections our view of their duties differs; as to the second it may be pointed out that under different management Kensington Gardens are practically free from the pest. It may also be added that no tramp can claim as a right the use of half an acre of land in the most costly part of the metropolis for a bedroom, and that the hardship involved in expelling him would be inflicted on individuals rather than on a class. There are many loafers in Hyde Park, but they are a mere drop in the ocean of London misery and can assuredly dispense with such a resting place, as thousands of their fellows do. With the condition of Hyde Park at night we do not propose to deal now. It is a well-known scandal to London, although public safety has recently been slightly protected by the fitting up of electric lights along some of the thoroughfares. In conclusion, however, we submit that, without going into details of the purposes for which the parks are dedicated to the public, these purposes do not include the practice of immorality by night or their use as dosshouses by day.

FARRIERY.

A CONTRIBUTOR to *La Semaine Vétérinaire* is wittily anxious to prove the exceeding importance in every commonwealth of efficient farriery. In France horses are estimated to be worth a milliard and a half of francs, but unless properly shod the animals could do no work and this enormous capital would consequently yield no revenue. In support of his serio-comic contention the writer quotes as follows from a work by M. Delpérier: "Suppress by a thought every mechanic in the world; agriculture would still suffice for the maintenance of mankind. Suppress the butchers and the bakers; the nations would nevertheless continue to exist. Suppress all the veterinary surgeons; their disappearance would scarcely be noticed. Suppress the men who treat the diseases of their fellow creatures; the latter in all probability would be no worse off than before. Suppress the lawyers, the journalists, the members of every Parliament without exception; the result would doubtless be, on the whole, advantageous. But do not dream of suppressing the farrier, for if you did horses could no longer work, agriculture would become impossible, and the human race would die of inanition."

THE POISONOUS SUBSTANCES BILL.

WE fail to see how this Bill, the substance of which, on the occasion of its second reading on the motion of the Duke of Devonshire in the House of Lords on June 24th, was given in our Parliamentary columns last week, is likely to afford much more protection to the public against the indiscriminate sale of poisons than at present obtains. It does not at any rate increase the scope of action under the Pharmacy Act which so far as it has related to the poisons placed within the Schedule has worked not with that completeness which might be desired but still with a fair measure of success. According to the provisions of the Bill carbolic acid (and with it its homologues), which by reason of the ease with which it can be purchased at oil-shops has been responsible for an enormous increase in the number of self-inflicted and, we need not add, most painful deaths, is still to be procured from any class of shop where the shopkeeper chooses to sell it, with, however, the restriction that the purchase is to be labeled distinctly with the word "poison" and with the name and address of the person selling the substance. Such a clause provides very well against the risks of accidental poisoning, but it does nothing for the deliberate suicide. Indeed, it only advertises the fact, it seems to us, that certain mixtures are poisonous. Surely the principle of scheduling certain substances as legally recognised poisons is a sound one to go upon if any hope at all is to be entertained of ever putting a stop to the indiscriminate sale of poisons. The seller should be registered and should be a person who knows exactly the nature of the commodity with which he is dealing and should possess an intelligence which will enable him to an extent to discriminate between purchasers who require the substance for a wrong or a right purpose. But it is urged that if the sale of such things as carbolic acid, disinfectants, and weed-killers, poisonous commodities which are in request every day, was restricted to persons possessing a proper qualification it would cause considerable inconvenience to the public by imposing a difficulty in the way of

Digitized by Google

obtaining these extremely necessary articles, and, again, that it would mean the transfer of a source of business and profit from the ordinary shopkeeper to the druggist. In the interests of the public why should not this be so when instance upon instance is on record of an ordinary tradesman having supplied with disastrous results carbolic acid in cups, ginger-beer bottles, black bottles, or any receptacle commonly used for containing beverages? The fact is that carbolic acid is a comparatively recent addition to commercial commodities, and its introduction on the market occurred some time after the passing of the Pharmacy Act, as otherwise without doubt it would have been included as a scheduled poison. We do not attach much force to the argument that such restrictions would lead to an abandonment of sanitary measures by the public owing to the *modus operandi* which would be enjoined in order to effect a purchase. There are plenty of excellent disinfectants which are comparatively non-poisonous, indeed, which would be practically free from harm; but carbolic acid is a poison of a powerful kind, and it is monstrous that its sale to the public has hitherto been as unrestricted as that of sugar. If a really protective measure is to become law the Bill introduced by the Duke of Devonshire and now read a second time in the House of Lords must be very seriously altered and amended. Otherwise the undoubted good which the present Pharmacy Act is doing will be to a great extent nullified.

DOCKRELL *v.* DOUGALL.

THE action of Dockrell *v.* Dougall, which was tried recently by Mr. Justice Ridley and a jury, shows that with all their merits the representatives of "the county" are singularly unable to appreciate the nature of professional reputation and of those influences which tend to injure it. Dr. Dockrell had complained of the use of his name in connexion with a certain medicated water sold by the defendant as a "pleasant health-preserving and health-restoring beverage that suits all constitutions." It seems that Dr. Dockrell, unfortunately for himself, had spoken well of this water in a particular case and had prescribed it under certain conditions in some other cases. These facts appeared in an advertising circular in the following guise: "Dr. Burnet, Physician to the Duke of York, Dr. Morgan Dockrell, Physician to St. John's Hospital, and many of the leading physicians, are prescribing 'Sallyco' as an habitual drink. Dr. Dockrell says: 'Nothing has done his gout so much good.'" The jury which tried the case, being unable to discern the injury which such an announcement was calculated to do to Dr. Dockrell's professional reputation, found that the words were not defamatory, with the consequence that an injunction to restrain the continued publication of the paragraph complained of was refused. It is not very likely that anything that we can say in these pages will have much weight with British juries—upon which medical practitioners do not serve—but it is nevertheless our duty to record a protest against the undiscerning treatment, which this case illustrates afresh, of medical men where their professional duties and professional rights are concerned. If Dr. Dockrell had made himself a party to the advertisement in question he would have committed an outrage against professional etiquette for which he might well have been subjected to professional discipline. And this rule exists for the protection, not of medical men, but of the general public. The medical profession could not possibly discharge its duty to the public if it did not carefully arm itself against the temptation to seek success by the tradesman's methods. In making this remark we cast no aspersion upon tradesmen. We mean, and mean only, that a man whose duty it is to consider what it is best for his patient that his patient should take would fall badly short of that duty if he entertained the consideration what it would be best for himself to administer or to recommend. A tradesman thinks only, and quite properly, what goods it will best pay him to sell, and if he can persuade his customer to buy those goods it does not concern him to inquire whether they are the best from his customer's point of view. He says, and says rightly, that of that his customer is the best judge. That is perfectly upright, perfectly honourable, wholly irreproachable, but it is not the professional point of view. That is the position of the tradesman as against his customer. But the position of the professional man with regard to his patient is wholly different. The patient relies upon his medical attendant's superior knowledge and disinterested care for his, the patient's, well-being. He wants advice, not goods, and would quite properly regard as tainted any advice which was prompted, like a tradesman's puffer, by an enlightened view of the caterer's own interest. The suggestion of quackery, in whatever form conveyed, has therefore always been, and we hope always will be, prejudicial in the highest degree to the medical practitioner. It is very unfortunate that questions of this kind should have to be submitted to a tribunal which consists mainly of tradesmen, for there can be no such thing as quackery in trade, and jurymen are apt to suspect that there is some lack of reality in an ethical doctrine to which their every-day experience assigns no significance. Ever since the days of Lord Langdale medical men have laboured under a serious disadvantage in defending their professional reputations, but as the celebrated case of Clark *v.* Freeman, in which that judge laid down the startling doctrine that the court would not grant an injunction to protect a medical man against the aspersion of being the author of a quack prescription, has seldom been cited in recent times, except to be disapproved, we had hoped that a juster appreciation of the rights of medical men in their reputations would now prevail. Unfortunately, the case of Dr. Dockrell proves that legal prejudices die very hard and that it is yet too soon to reckon upon relief in such a case from the courts of law. It took a recent Act of Parliament to sweep away an old dictum and give to a woman whose chastity had been aspersed a right of action for defamation in that form; we trust that somewhat less violent means may be found sufficient to place medical men upon a level in respect of the defence of their reputations with their more fortunate neighbours.

THE SMOKE NUISANCE.

PUBLIC measures continue to be taken, it is gratifying to record, towards the suppression of the smoke nuisance of which we have repeatedly complained in these columns for now nearly three years. We cannot regard the nuisance as one having newly appeared or only since the Welsh strike. As early as September, 1895, in THE LANCET we remarked that the Section in the Public Health Act providing against the emission of foul smoke into the air was practically without effect. It is with some satisfaction therefore that we are able to state that the authorities have at last been stirred up to a sense of their responsibility in this matter. The nuisance has doubtless been accentuated by the fact of the Welsh strike, Welsh coal being a hard, brittle coal, which burns without much smoke. But, as we have already pointed out, the clause in the Public Health Act was obviously aimed at securing certain structural arrangements of the furnace or fireplace which would deal with smoky coal. A deliberate evasion of the requirements of the Act is admitted therefore, it seems to us, by those who plead in defence that the nuisance was created in consequence of the inability to get smokeless coal. In other words, now

Digitized by Google

that only smoky fuel can be obtained the furnaces are found to be in fault and it has remained for the Welsh strike to bring this fact to light. It is a source of satisfaction to ourselves, however, that a distinct note of warning has been issued. Last week we recorded a case in which a conviction was obtained and a penalty imposed, the usual defence of the difficulty of getting Welsh coal being adopted—a line of defence, we are glad to say, which did not appeal to the magistrate. This week, at Greenwich, the Thames Steamboat Company was summoned for a similar offence caused on the river by one of their steam vessels. The defence urged was again the same—the Welsh strike—but the magistrate, Mr. Kennedy, imposed a fine of £5 and £6 9s. costs. We notice with satisfaction that the matter has also been taken seriously in hand by the City authorities. In his report on the sanitary condition of the City of London for the year 1897 Dr. W. Sedgwick Saunders devotes considerable space to the smoke nuisance and particularly that caused by restaurants and houses of public refreshment. In sixty-three cases the inspector served official notices or warnings. Forty-six of these were reported to the Sanitary Committee and six prosecutions were instituted, "but the convictions have been unimportant and certainly not prohibitory." We entirely agree with Dr. Saunders's concluding paragraph, that "in large buildings in which steam boilers are used the smoke nuisance can be dealt with in a different spirit and no rational excuse can be found for any infraction of the law, which directs that the owners shall avail themselves of the best engineering skill in combination with the most suitable fuel as the best means of preventing the vomiting forth into the atmosphere of volumes of dense smoke to the annoyance of their neighbours, the obstruction of daylight, and injury to property." Notwithstanding this the electric lighting stations in the metropolis are amongst the worst offenders. We trust that we shall continue to hear of the unabated efforts of our sanitary authorities to suppress a nuisance for the continuance of which there is not a shadow of excuse.

ULCERATING GRANULOMA OF THE PUDENDA.

IN the *British Guiana Medical Annual* for 1896 a paper by Mr. Conyers and Mr. Daniels appeared on "The Lupoid Form of the So-called 'Groin Ulceration' of this Colony." In this paper the writers gave an account of a disease which seems to be fairly prevalent in the West Indies, though it is probably more widely spread, but only in the tropics. It attacks first in males the skin of the pubes or the groin and in females the labia or vagina, though it may extend later from one iliac spine to the other. It commences by the formation of papules which by increase in size become nodules; these may break down and ulcerate. Cicatrisation may occur, but the scars are not healthy and are prone to break down again. One case has recently occurred in England and has been under the care of Dr. J. J. Pringle at the Middlesex Hospital. An important addition to the scanty knowledge of the disease has been made by Dr. James Galloway, who has contributed a paper on the subject to the *British Journal of Dermatology*. He has examined microscopically portions of the growth sent to him by Mr. Daniels and in this paper he has described what he has found and has given some excellent coloured illustrations. The disease begins with a small-celled infiltration in the upper part of the corium and in the papillæ, then the interpapillary epidermal processes increase in length greatly, the connective tissue of the corium disappears, so that large masses of the small-celled exudation underlie the elongated epithelial columns. There is no tendency to caseation or to suppuration in the infiltrated masses; in the older parts of the growth the cells disappear and their place is taken by newly-formed connective tissue. The absence of giant cells and the negative results of inoculation on guinea-pigs both clearly distinguish it from tubercle; the failure of anti-syphilitic remedies and the absence of other syphilitic manifestations are strongly opposed to the disease being syphilis. There is much resemblance to yaws, but the points of difference are sufficient to justify the assertion that the two diseases are distinct. It may be considered certain that though the disease probably belongs to the infective granulomata yet it is not identical with any of the granulomata with which we are familiar.

CYCLISTS' SORE-THROAT.

AFTER a "spin" along a more or less dusty road the cyclist sometimes experiences a dry and subsequently sore and inflamed throat. Headache and depression often follow and the symptoms generally simulate poisoning of some kind. When the bacteriology of road dust is considered these effects are hardly to be wondered at. Hundreds of millions of bacteria according to the nature of the locality are found in a gramme weight of dust and the species isolated have included well-known pathogenic organisms. Indeed, there can be no reason for doubting the infective power of dust when it is known that amongst the microbes encountered in it are the microbes of pus, malignant œdema, tetanus, tubercle, and septicæmia. The mischief to riders as well as to pedestrians would probably be largely averted if, as nature intended, the respirations were rigidly confined to the nasal passages and the mouth kept comfortably though firmly shut. As investigators have shown, the microbes in the air seldom pass beyond the extreme end of the nasal passage, and consequently never to the pharynx or bronchial surfaces. A useful precaution, therefore, in addition to exclusively breathing through the nostrils would be to douche the nasal cavity after a dusty run or walk with a weak and slightly warm solution of some harmless antiseptic.

CORPORAL PUNISHMENT IN BOARD SCHOOLS.

THE average School Board may very well hope to inherit the blessings promised to those who are evil spoken of, for it is most certainly not a popular body. A case which recently occurred at Laurencekirk shows very well the unfortunate tendency which School Boards have of doing the right thing in the wrong way and also how they have entirely failed to impress parents with the necessity of giving obedience to authority. School Boards are for good or ill part of the legal machinery of the land—they have duties to perform as well as responsibilities to carry out. The case in question arose in the following way. A printer named McLaren and his wife had, according to the report in the *Aberdeen Free Press*, "complained to third parties that one of their children had uttered a swear in the street one day. This had been reported at the school and corporal punishment, it was said, followed." The punishment was administered by an assistant teacher and Mrs. McLaren thereupon wrote a very foolish and offensive letter to the teacher in question. The head-master, to whom the matter was reported, refused to allow the McLaren children to attend school until the parents apologised. The parents did not apologise, the children did not return, and the parents were then summoned before the Board as defaulters. Eventually McLaren apologised for the letter, but afterwards withdrew his apology and was fined. The sequel to this petty squabble was that the minds of both McLaren and his wife gave way, so that they had to be removed to an asylum. Now we do not in the least question the right of School Board authorities to inflict corporal punishment upon unruly children and we would heavily fine the irate parent who assaults teachers for punishing children. But we do not think it right for assistant teachers to have power to inflict corporal punishment — that should be the prerogative of

Digitized by Google

the head-master alone. In no one of the great public schools of England, we believe, have any assistant masters the right to flog, though very occasionally the power is delegated to them. Perhaps an exception ought to be made in the case of the Lower Master at Eton and the Usher at Uppingham in olden times, but these gentlemen acted as delegates of the head-master. So much for one error in judgment. Again, could anything have been more foolish than for the Board first to prohibit through their officer the re-entry of the children to school and then to summon the parents for not sending their children to school. And what is the end of it all? The parents are in the asylum at a cost of £66 per annum to the parish and the children are in the workhouse at a cost of some £40 per annum. And all might have been avoided by the exercise of a little of that common-sense in which the Scots nation is by no means lacking.

THE PROPOSED EXTENSION OF HAMPSTEAD HEATH.

IT is gratifying to know that a few of the public-spirited inhabitants of Hampstead have taken steps to save Golder's Hill from the hands of the speculative builder. The proposed extension of Hampstead Heath as an open space is a matter of public moment. It has for the medical profession a special interest as it would secure for all time the site of the property of the late Sir Spencer Wells for public use as a part of the heath. This property, extending over 36 acres, has been bought for £38,000. It is understood that it can easily be sold again for more money to the voracious builders. But we may hope that the public and the County Council together will permanently avert such a catastrophe which in the meantime is temporarily averted by the action of the guarantors. Men with money can scarcely put it to better use than by subscribing to this end. Sir Spencer Wells used to say with pride to his guests—and they were "a numerous host" of all classes and nations and creeds—that he could see as far as Windsor Castle from his grounds. It would be a pity to let the chance slip of saving such views for the workers of London.

TYPHOID CHOLECYSTITIS AND CHOLELITHIASIS.

THE *Johns Hopkins Hospital Bulletin* for May, 1898, contains an important paper on this subject by Dr. H. W. Cushing. In an annotation in THE LANCET of June 12th, 1897, we called attention to the frequency of invasion of the gall-bladder by the typhoid bacillus and the consequent cholecystitis. Dr. Cushing's paper contains some additional facts of great interest. It appears that the gall-bladder, like Peyer's patches, is a site of election for the typhoid bacilli. In 1891 Blachstein noticed their constant occurrence in the gall-bladder of rabbits after experimental inoculation. Later, Professor Welch discovered that they persisted in this situation; in one animal they were found 128 days after inoculation, when they had disappeared from every other organ. Acute cholecystitis may appear in the late stage of typhoid fever, but there is a group of cases in which it appears some months after the attack and always in association with cholelithiasis. The connexion between typhoid fever and cholelithiasis was first pointed out in 1889 by Bernheim and has been confirmed by several writers. In Professor Halsted's clinique in the Johns Hopkins Hospital 10 out of 31 cases of cholecystitis with cholelithiasis which were operated on gave a history of typhoid fever, the interval varying from a few months to twenty years. Such a long interval by no means negatives the connexion, for the bacillus has been found in a case of cholecystitis as late as fourteen years after an attack of typhoid fever. Similarly abscesses of bone may follow typhoid fever after long intervals; in a case recorded by Buschke the interval was 46 years and yet the bacillus was cultivated from the pus. These cases well illustrate that the germs of disease may remain latent in the body for an indefinite period—a doctrine which is only beginning to be appreciated and which has far-reaching possibilities. Dr. Cushing reports a remarkable case of cholecystitis and cholelithiasis in which cholecystotomy was performed and the typhoid bacillus found in the gall-bladder, although there was no history of previous typhoid fever. The blood-serum gave the typhoid reaction. The widespread occurrence of the typhoid bacillus has only been lately recognised. In 1892 Guarnieri first described an infection of the biliary passages, liver, and spleen without intestinal lesions.

A NEW BACILLUS IN MILK.

DR. CAMPBELL MCLURE of Glasgow describes in the current number of the *Deutsche Medicinische Wochenschrift* a bacillus which he discovered while making examinations of milk in the laboratory of Dr. Piorkowski in Berlin. In the agar plate cultures it formed brown granular colonies, which also grew well in glycerine agar at 37° C., presenting a white appearance, confluent in the middle and punctate at the margins, and becoming yellow and slimy in three or four days. Milk treated with the bacillus and kept at 37° C. for 48 hours was coagulated and had a strongly acid reaction and an acetous smell. The appearance of a bouillon culture kept for 24 hours at 37° C. was constant and typical, the fluid being slightly turbid with a considerable flocculent deposit on the bottom and sides of the tube. The bacillus could be stained with the ordinary aniline colours but not with Gram's solution. Cover-glass preparations stained with methylene blue showed a great similarity to the diphtheria bacillus and the pseudo-diphtheria bacillus of Löffler and von Hofmann respectively.

IGNORANCE AND HEROISM.

A CASE came up before the Holsworthy District Council on June 29th which revealed an inconceivable degree of inhumanity and ignorance. A boy named John Gerry was in the employ of a farmer, by name Dufty, of The Barton, Ashwater. Dufty had only recently—i.e., Lady Day—removed to The Barton and had previously lived at Croft, in Halwill. At Croft there had been cases of typhoid fever and the medical officer of health considered that the infection had been carried from Croft to The Barton by means of bedding. About June 7th Gerry was taken ill and the illness eventually proved to be typhoid fever. His employers refused to nurse him at all. Mr. E. O. Kingdon managed to get a trained nurse from Exeter, who nursed Gerry for two days and nights, after which she was naturally exhausted. Mr. Kingdon nursed him for one whole day and the rector, the Rev. G. D. Melhuish, sat up for three days and nights. Eventually it was thought best to remove the boy to Exeter, which Mr. Kingdon did, mainly at his own expense, telegraphing for an ambulance to meet him at Exeter. The poor boy died on the night of his admission to the hospital. It is, of course, a risk to move a patient in the third week of typhoid fever, but what else could have been done? Mr. Kingdon did what he could, but that is all part of the day's work for a medical man; and will it be believed that a sapient district councillor considered that Mr. Kingdon had committed an "error of judgment"? The attitude of Mr. Kingdon and the Rev. G. D. Melhuish deserves all praise. With regard to the former, as we said before, he did what many another medical man has done, and will do again; but though Mr. Melhuish did no more than his duty it was harder for him, being non-medical, to act as he did, and his name will be reckoned in the same category with Mompesson of Eyam, with Father Thomas.

who ministered to the fever-stricken in the dungeons of Morocco, and with Bishop Belzunce in the plague at Marseilles.

BACTERIOLOGICAL EXAMINATION OF WATER.

THE official report upon the recent epidemic of enteric fever at Camborne, which we reviewed in THE LANCET of July 2nd, leaves no doubt that the outbreak was due to specific pollution of the Camborne public water-supply. From appendices to the report we learn that on Dec. 15th, 1897, at a time when this water was no doubt still distributing infection, a sample was sent to a firm of chemists for analysis. The chemists having reported, as was proper, upon their examination of the sample, concluded with the opinion that "this water is well suited for drinking and domestic purposes." On Dec. 17th a sample of the same water, no doubt still distributing infection, was sent to an association in London for bacteriological examination. The bacteriologist, after reporting, as was proper, upon the organisms contained in the sample, also concluded with the opinion that this water should be "looked upon as fit for drinking purposes." The case affords a striking illustration of the danger of pronouncing a water wholesome on the strength of laboratory examination of a single sample and deserves to be considered by all chemists and bacteriologists who are concerned with the examination of water. Further, the importance of always associating a thorough investigation of the source of the water with both a chemical and bacteriological examination is again illustrated.

SYRINGOMYELIA WITH SYMPTOMS OF ACROMEGALY.

AT the January meeting of the "Gesellschaft der Neuropathologen und Irrenärzte"[1] in Moscow Dr. M. A. Luntz described the case of a woman, thirty years of age, who for three years had suffered from pains in the right upper extremity. Swelling and weakness gradually affected the limb with analgesia and thermo-anæsthesia leading to frequent burns of the extremity. There were also inflammatory affections of the fascia and subcutaneous tissues which occurred without pain. Within the previous year there had also been pains and loss of sensibility of the left upper extremity, of the chest and upper part of the back. There was no neurotic element in the patient's personal or family history. She was of sturdy build with considerable development of subcutaneous fat. There was considerable increase in the circumference of the right upper extremity, especially in the lower third of the forearm and the hand. The enlargement involved the bones as well as the soft parts—an observation confirmed by the Roentgen rays. On the hinder part of the head, the neck, on both upper extremities, on the chest and the back as low down as the ninth dorsal vertebra there were sensory disturbance, analgesia and thermo-anæsthesia, with retention of sensibility for touch and pressure. Below the level mentioned the sensibility was quite normal. There was weakness of both hands, especially of the right, and on this hand were numerous scars from burns. On the palmar aspect of the right thumb was the scar of a deeper inflammatory process and the right index finger was contracted in consequence of an inflammation affecting the tendon. There were signs of trophic disturbance all over the anæsthetic area and evidence of interference with the vaso-motor arrangements of the extremities. The knee-jerks were rather active, the electrical irritability of the upper extremity was diminished to each current, the sphincters were unaffected, and all the internal organs seemed to be normal.

[1] Neurologisches Centralblatt, June 15th, 1898, p. 564.

There seems no reason to doubt that Dr. Luntz is right in regarding the case as one of syringomyelia affecting the cervical and upper dorsal part of the cord. The peculiarities of the case consist in the absence of any very obvious muscular wasting in the upper extremities—signifying that the anterior horns have as yet suffered but slightly, if at all—and in the distinct enlargement of the whole right upper extremity. The cause of this peculiarity—which has been described also by other observers—is not by any means clear.

THE DISPENSING OF MEDICAL PRESCRIPTIONS BY DRUGGISTS.

IN spite of the advances which medical science has made within recent years the medical practitioner when he prescribes for his patient is sufficiently conscious of the prominent place which the element of the unknown still occupies. There are, however, certain factors which he regards as reliable and trustworthy and one of these is the belief that whatever he prescribes will be accurately made up. Certain analyses, however, which have recently been made by Dr. Alfred Hill in the city of Birmingham would seem to indicate that a careful supervision of druggists in this particular is necessary. Out of 60 samples examined no less than 23 per cent. differed so much from the prescription that they were certified as adulterated. 52 of the samples were obtained from qualified pharmaceutical chemists and of these 11 were condemned, while of the remaining 8 samples procured from unqualified vendors 3 were condemned. To go a little into detail we find that of 7 samples of iodide of potassium and cinchona mixture 4 only were of correct composition. So, too, of 4 samples of quinine mixture 3 contained a slight excess of the drug and the fourth an excess of 18 per cent. Camphor liniment was ordered on 15 occasions, and in 4 samples there was found only from 50 to 75 per cent. of the camphor which should have been present. 4 samples of iron and quinine pills were procured and in one of them an excess of no less than 80 per cent. of sulphate of iron was found. Of glycerine 12 specimens were analysed and in 4 traces of arsenic—too much to be regarded as an adulteration—were detected. 2 samples contained dilute glucose-syrup in large quantities.

NEUROTIC SEQUELÆ OF FEVER.

IT is well to remember that even the milder forms of infectious exanthemata are capable of grave developments. In the case of measles this does not appear to be very remarkable when we consider the frequently severe type of the disease, though the occurrence of such complications as myelitis, peripheral neuritis, and even a form of paralysis resembling disseminated sclerosis, all of which have been recorded, is at once recognised as exceptional. The mention of chicken-pox is usually suggestive of something which may safely be neglected, and, happily, the absence of methodical treatment does not in most cases entail any grave consequences. It is not to be forgotten, however, that in this disease not only do we occasionally meet with symptoms of unusual intensity, but also with neurotic sequelæ identical with those observed in the severer infectious fevers. Thus peripheral neuritis has been recorded among the sequelæ of varicella and M. Bouvy, in the *Journal de Clinique et de Thérapeutique Infantiles* of June 23rd, 1898, describes a case of partial paralysis with some of the characters of multiple sclerosis observed in an infant three years old while convalescent from varicella. It was said that a year previously to this attack the child suffered from some form of eruptive fever. A slight facial paralysis with weakness in walking were noticed for a few days subsequently. These symptoms appeared to have passed off, but returned again in a more marked form after the varicella. Observations on

Digitized by Google

this subject are still too few to justify any attempt at generalisations, but such as we have are at least suggestive. As far as they go they encourage a belief that the connexion between fever and consequent neuroses is not entirely limited to the case of the severer forms of infectious disease. It is probably to some extent also an effect of idiosyncrasy, marking both the activity of nerve processes, whether in the course of growth or functional employment, and the measure of nerve resistance.

INTRAVENOUS INFUSION IN URÆMIA.

THE doubts which always exist as to a so-called good result reported of any mode of treatment are to a great extent removed when this result follows the failure of other methods. Such cases as the following, published in the *Boston Medical and Surgical Journal* of May 26th, 1898, by Dr. B. Metzger, are always of value as evidence. A child, aged six years, complained of abdominal and lumbar pain, passed a few cubic centimetres of bloody urine, containing hyaline and granular cysts, and vomited several times in the evening. Diuretics were given and hot packs were applied. On the following days the quantities of urine passed were 65, 65, 150, 40, and 10 c.c. He vomited once every ten minutes night and day. He steadily lost ground, became delirious and then comatose. The pulse was slow but of good volume. As a last resort 10 oz. of blood were taken from the median basilic vein and 20 oz. of normal saline solution were infused. In an hour he was conscious and nine hours afterwards he passed 100 c.c. of urine and in the next five hours 670 c.c. Hot packs, digitalis, squills, &c., had been given a faithful trial. This case bears out, what is far from generally appreciated, that water is the best diuretic in renal disease though the improvement was perhaps partly due to the blood-letting.

THE MANCHESTER AND SALFORD SANITARY ASSOCIATION.

WE should like to see sanitary associations formed in all places where the population being fairly great very much depends upon the efficient application of sanitary measures. Such bodies can do an excellent work, can watch over the well-being of their fellow inhabitants, and represent to the proper authorities any defects which have appeared as a result of their own observations and inspection. Indeed, could such a movement be universally adopted much good for the community at large would be done. Our remarks are prompted in particular by a report which we have recently received from the Manchester and Salford Sanitary Association, the perusal of which affords us a case in point. Amongst the subjects recently investigated at the instance of the association, for example, are the disposal of the town's sewage, the use of preservatives in food, the sanitary condition of bakehouses, dangerous paraffin lamps, and chemical nuisances. As the result of an inquiry undertaken by Mr. William Thomson, F.R.S. Edin., F.I.C., on the petroleum lamp accidents question he points out the great danger of a certain lamp which appears to be much in use in Manchester and the neighbourhood, 75 per cent. of the explosions investigated being due to the defects of this particular burner. He concludes that "a good lamp might by accident or carelessness be rendered a dangerous one and it is therefore of the utmost importance that we should follow the example of many of the American States and prevent the importation of oil having a lower flash-point than 100° Fahrenheit." We may remark that the importation of oil having a lower flash-point than 100° F. cannot be prevented in view of the great and indispensable application of oil of a lighter character in the arts and industries. A restriction of the sale of lamp-oil of a lower flash-point than 100° F. has been recommended by a Parliamentary committee, but we doubt whether, even if adopted, the measure will be found practicable. Further, what applies to the possibilities of a good lamp "by accident or carelessness" becoming a dangerous one applies equally to an oil of 100° F. flash-point.

A MEETING of the Executive Committee for the institution of a Jenner Memorial was held at St. George's Hospital last Monday afternoon, when the President, Lord Lister, was able to announce the gratifying news that £10,000 had been subscribed, Lord Iveagh being responsible for the noble donation of £5000.

A CONVERSAZIONE will be held under the auspices of the medical staff and the lecturers of the Dental Hospital of London at the Royal Institute Galleries, Prince's Hall, Piccadilly, on Tuesday, July 19th, 1898. The prizes in connexion with the school will be distributed by Lord Ludlow at 8.30 P.M.

THE distribution of prizes to the successful students at Charing-cross Hospital Medical School will take place on July 20th, Mr. T. McKinnon Wood, chairman of the London County Council, presiding.

WE understand that under the will of the late Sir Robert Rawlinson, chief engineer inspector of the Local Government Board, St. Thomas's Hospital receives a legacy of nearly £35,000.

THE Executive Committee of the General Medical Council will meet on the 12th inst. and the Penal Committee on the 13th inst.

AT the recent meeting of the governors of Wellingto College Sir Joseph Fayrer, Bart., K.C.S.I., &c., was elected a governor of the College.

THE ROYAL ARMY MEDICAL CORPS.

THE following is the text of the Royal Warrant authorising the formation of a Royal Army Medical Corps:—

ROYAL WARRANT.

FORMATION OF THE ROYAL ARMY MEDICAL CORPS.

VICTORIA R.I.

WHEREAS We have deemed it expedient to alter in certain respects the conditions under which officers employed upon the medical duties of Our Army are at present serving;

Our Will and Pleasure is that the officers below the rank of surgeon-major-general serving in our Army Medical Staff shall be formed into a corps together with the warrant officers, non-commissioned officers, and men of Our Medical Staff Corps;

It is Our further Will and Pleasure that the designation "Medical Staff Corps" shall be abolished and that the Corps formed as above mentioned shall be styled the "Royal Army Medical Corps."

The following alterations will consequently be made in the ranks of the medical officers of Our Army:—

Present Ranks.	New Ranks.
Surgeon-Colonel	Colonel.
Brigade-Surgeon-Lieutenant-Colonel / Surgeon-Lieutenant-Colonel	Lieutenant-Colonel.
Surgeon-Major	Major.
Surgeon-Captain	Captain.
Surgeon-Lieutenant	Lieutenant.

The medical staff of Our Army shall in future consist of

Digitized by Google

Surgeon-Generals (ranking as Major-Generals) and the title of Surgeon-Major-Generals now serving shall be altered accordingly.

Officers of Our Royal Army Medical Corps holding appointments in Our Household Troops shall be borne as second officers on the establishment of Our Royal Army Medical Corps and shall be dealt with as regards pay and promotion in accordance with the rules laid down in Articles 384, 385, and 387 of Our Warrant for the pay, appointment, promotion, and non-effective pay of Our Army, dated 26th April, 1897.

Given at Our Court at Windsor this 23rd day of June, 1898, in the 62nd year of our Reign.

By Her Majesty's command,

Army Order 93 of 1898. LANSDOWNE.

THE BRITISH PHARMACOPŒIA.

VII.[1]

THE ADDITIONS *(continued)*.

Glycerinum Acidi Borici.—This is a misnamed preparation: it is a compound, a borate of glycerol, not a mere solution of boric acid in glycerine, as its name suggests. It is the Glyceritum Boroglycerini of the United States Pharmacopœia and it now becomes the official representative of the well-known "Boroglyceride," a patented substance used for the preservation of milk, butter, and various foods. It is soluble in water and may be used as a surgical dressing or administered internally in pills or cachets.

Glycerinum Pepsini.—This is a very desirable addition and forms an active preparation, one fluid drachm of which represents 5 gr. of pepsin. It may be administered in the undiluted state in atonic dyspepsia and it has been employed as a paint with the view of destroying the false membrane in diphtheria. The pepsin preparations have of late years given way before papain, as this vegetable digestive acts in an alkaline medium. It is hardly necessary to remind our readers that preparations like the one under notice cannot be employed as a means of peptonising foods, though some of the best text-books err on the subject. If the glycerine of pepsin be added to food before swallowing the digestion leads to the formation of most evil-flavoured by-products which the patient's stomach would be certain to reject; it must therefore be given after a meal or with the food. It can be employed, however, with advantage as an agent for predigesting nutrient enemata, but the following is preferable in every way.

Liquor Pancreatis.—This is a liquid preparation containing the digestive principles of the fresh pancreas of the pig, being most active when the animal from which the pancreas has been obtained has been fed shortly before being killed. 5 oz. of pancreas freed from fat and external membrane and finely divided by trituration with washed sand or powdered pumice-stone should be digested in a closed vessel with 1 pint of 20 per cent. alcohol for seven days and then filtered. It may be regarded as the official representative of the well-known liquor pancreaticus (Benger).

The pancreas contains at least four ferments—viz., trypsin which changes proteids into peptones in the presence of alkalies or in a neutral medium; a second—the curdling ferment—coagulates the casein of milk; the third—the emulsifying ferment—emulsifies or partially saponifies fat; whilst the fourth—the diastatic ferment—changes starch into sugar and dextrin. The new official liquor contains at least three of these ferments.

The use of digestive agents in affections of the stomach and various wasting diseases is of the greatest assistance to the physician in treating these disorders, and therefore this addition to the British Pharmacopœia will be hailed with satisfaction. It is, however, essential that a few cardinal points in chemical physiology be remembered before they can be successfully employed in the treatment of disease. Owing to the acid reaction of the normal gastric secretion the pancreatic ferments do not exert their digestive properties on the contents of the stomach, and as they are also rapidly destroyed by the gastric juice before reaching the duodenal alkaline liquids it is useless to administer them with the intention of aiding digestion. Their use in therapeutics must therefore be confined (with one exception) to the predigestion of various foods before administration. By the addition of the liquor pancreatis and a small quantity of sodium bicarbonate, milk, gruel, beef-tea, soups, and farinaceous foods of various kinds can be peptonised—that is, may have their proteid constituents changed into soluble peptones before administration.

If the peptonisation process be carried out to completion then, as in the case of pepsin, various nauseous and bitter by-products are generated which render the food so unpalatable that it cannot be swallowed. This may be easily prevented by checking the process before the bitter products are formed as in the usual manner of peptonising milk in the sick room. Thus two-thirds of a pint of fresh cow's milk are diluted with about one-third of a pint of water and the mixture is heated in a suitable vessel to about 120° or 140° F., when two drachms of the liquor and 30 grs. sodium bicarbonate are added and the whole is left standing in a warm place for about 15 minutes when it is ready for use. If the entire quantity can be administered without delay nothing more is necessary, but as this is not generally practicable the digestive or peptonising process must be stopped by bringing the food to the boiling-point, which destroys the trypsin, or by plunging the vessel in ice, which stops the process for the time. After boiling for a few moments the peptonised liquid will then keep without change for a considerable time and it may be used like ordinary milk for mixing with, or for making, other foods or dishes, as it is free from objectionable taste or smell. One or more teaspoonfuls of the liquor with a little alkali may be advantageously added to nutrient enemata before or at the moment of administration.

The exception already mentioned to the administration of pancreatic products by the mouth refers to the use of trypsin in intestinal indigestion and diabetes and where there is reason to suspect that the normal secretion of the pancreas is absent or in abeyance. In such cases trypsin may be made into pills which should be coated with keratin so that they may pass through the stomach unaltered. The alkaline bile or duodenal secretion will dissolve the keratin which is unacted upon by acids and will set free the ferment which then supplements the pancreatic secretion.

Various preparations are procurable which are said to contain the emulsifying ferment of the pig's pancreas. They are prepared by dissolving out the pancreatic fat by ether and making an emulsion with alcohol. They are recommended in phthisis where the digestion of animal fats is supposed to be at fault. Only the liquid containing the peptonising, curdling, and diastatic ferments is official.

No doubt papain—the soluble ferment from *Carica papaya*—will be honoured by a place in the next revised Pharmacopœia. Its great advantage lies in its power of changing proteids into peptones in an acid, neutral or alkaline medium. In various diseased or disordered conditions of the stomach where digestion is in abeyance in the presence of large amounts of butyric and other irritating acids and where large doses of alkalies are indicated papain can be administered with very striking results. In such cases pepsin is useless and of course pancreatic ferments are inert, but after the neutralisation of the objectionable acid by the alkali the papain hastens or finishes the digestive process and gives the irritated and pained stomach valuable rest. Papain, pepsin, and pancreatic ferments have been used as local agents for the destruction of the false membrane in diphtheria and for stimulating the healing of ulcers, but the results are unsatisfactory.

Infusum Scoparii.—Many changes have been made in the group of infusions by the revisers, as mentioned in the article on the "Omissions," where we commented upon the rejection of 7 of these preparations. Several changes in the time, strengths, and dosages have also been made, but in no case are these changes of such importance as to come under the scope of the present article. The infusion of broom is introduced to take the place of the old decoction; its strength is doubled and the dose is only one-half of that of the older preparation. Doubtless the revisers had good reasons for the change and we hope that they made careful experiments upon the amount of active principles to be found in the old decoction and in the liquid made by the simpler process of

[1] Articles I., II., III., IV., V., and VI. were published in THE LANCET of April 16th and 23rd May 7th and 28th, and June 18th and 25th, 1898, respectively.

Digitized by Google

infusion. In immediate connexion with the group of infusions must be considered the new departure which has given to the British Pharmacopœia the following preparations: Liquor Chiratæ Concentratus, Liquor Calumbæ Concentratus, Liquor Cuspariæ Concentratus, Liquor Krameriæ Concentratus, Liquor Quassiæ Concentratus, Liquor Rhei Concentratus, Liquor Senegæ Concentratus, Liquor Sennæ Concentratus, Liquor Serpentariæ Concentratus, and Liquor Sarsæ Co. Concentratus.

These concentrated liquors are introduced as representatives of the class of concentrated infusions which have been for several years manufactured by wholesale houses and used occasionally by some dispensing hospital chemists as ready-made substitutes for the fresh infusions of the same name. The usual strength of the commercial article was such that 1 part added to 7 parts of water formed a solution equivalent to the fresh official infusion. These new British Pharmacopœia liquors are solutions of the active and flavouring properties of their respective drugs in dilute alcohol (20 per cent.) of such a strength that 1 part added to 9 of water forms a solution as nearly as possible equivalent to the official infusion. We must say that the introduction of this formidable list of preparations of drugs, for the most part of minor importance, is the feature which we like less than any change made by the revisers. To multiply Galenical preparations of drugs like cusparia, serpentary, or even krameria and chiretta, is an unfortunate mistake. There are, however, more grave objections to this new departure. The authorities responsible for the new British Pharmacopœia state in the preface to the volume that after experimenting with the object of preparing the 3 Decoctions and the 22 Infusions of the Pharmacopœia in highly concentrated states they obtained compounds resembling the liquids which manufacturers have termed "concentrated decoctions and infusions." "But some of these compounds underwent deterioration on keeping or were wanting in flavour or aroma and were accordingly rejected. Nine of the most successful have been admitted into the Pharmacopœia as *Liquores Concentrati* and the products of their dilution with water *may be prescribed by practitioners in place of the corresponding official infusions.*"

It will be noticed that the above extract from the preface does not give permission or rather does not legalise the use of these liquids by the chemist when dispensing the prescription of a physician who simply prescribes an infusion. There is, however, a difference of opinion upon this point and some chemists are labouring under the idea that when a mixture containing say 10 oz. of infusion of calumba is prescribed 1 oz. of the concentrated liquid should be used. We believe this to be a mistake, but it is most difficult to really know what the revisers mean by introducing these preparations with the understanding that they may be prescribed in place of the official infusions. The physician may order the corresponding tinctures in place of the infusions if he wishes and there is no necessity for a statement to this effect in the preface. The main consideration, however, is the important one that these liquors when diluted with water do not really represent an infusion at all. The British Pharmacopœia practically recognises this when it states that "the diluted *liquores* differ in minor respects from freshly prepared decoctions or infusions and contain a small quantity of ethylic alcohol." A *watery* solution of the principles of rhubarb root is a very different thing from a solution prepared by percolating the root with weak alcohol. The process for the calumba preparation is a very bad one, as no two samples can be found alike when prepared by maceration and pressure. They require about ten days for their preparation in nearly every instance, thus enormously increasing the cost. We have given only a few of the more serious objections to these liquors, which we are confident will seldom be prescribed by the physician and which if used by the dispenser will certainly lead to endless complaints on the part of the patient and to loss of confidence in both his chemist and medical attendant. We cannot but think that their introduction was a grave error in judgment and that they will be rejected in the next issue of the Pharmacopœia. With the exception of the infusion of digitalis the practitioner never prescribes an infusion except in the form of a vehicle to make the mixture up to a certain fixed bulk, as 6, 8, 10, or 12 oz. If he wishes to order these liquors he must prescribe them as he does a tincture and pause to make an elaborate arithmetical calculation of how much of them will correspond to the amount of fresh infusion which he is in the habit of prescribing.

Liquor Hamamelidis is introduced as a substitute for the popular Hazeline and Pond's Extract. It is to be made from the *fresh* leaves. The imported liquors with which the profession is familiar are made where the witch hazel flourishes and the *twigs*, as well as the leaves, of the tree are employed. How far the new official liquor will resemble the American preparations therapeutically remains to be proved at the bedside. By an oversight the dose of this preparation is not given, though the imported preparations are frequently administered by the mouth in doses up to 1 or 2 drachms. This addition will be, no doubt, extensively employed as a local application to hæmorrhoids and as an injection in hæmorrhage from the bowel and as a means of checking internal bleedings when administered by the mouth.

Liquor Hydrogenii Peroxidi.—This valuable agent has at last found official recognition. It is a colourless and odourless solution of hydrogen peroxide which should yield about 10 volumes of oxygen. It is a powerful antiseptic and bleaching agent and has been much used for changing the colour of dark hair to the light golden shade. It readily destroys the organised ferments without destroying diastase fermentation and already the number of diseased conditions in which it has been administered is very great though the results in the majority of instances are disappointing. It has been given in teaspoonful doses in diphtheria, measles, scarlet fever, fevers, and pertussis with the view of destroying the micro-organisms. As a local application to foul wounds and ulcers it is most valuable and it has proved highly successful in destroying the germs in purulent cavities and abscesses when injected with water (1 in 10). It occurs in Sanitas which is used as a general disinfectant.

Liquor Ethyl Nitritis is a colourless liquid containing from 2½ to 3 per cent. by weight of ethyl nitrite in alcoholic solution with 5 per cent. glycerine. In doses of from 20 to 60 minims it is a valuable relaxer of arterial spasm acting like nitrite of amyl and spirit of nitrous ether. It may be noticed that the official test for spt. æther nit. provides for a percentage of 2½ parts of ethyl nitrite in 100.

Lamellæ Homatropinæ are introduced for ophthalmic use to dilate the pupil. Each disc contains $\frac{1}{100}$ gr. of the hydrobromide; though weaker in action than atropine the effects pass off more rapidly.

Pilula Quininæ Sulphatis is a beautiful mass consisting of 30 gr. of the sulphate, 1 gr. of tartaric acid, 4 gr. of glycerine, and 1 gr. of tragacanth. We have already referred to the great value of the hydrochloride of quinine now made official for hypodermic injections.

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

THE twenty-eighth sitting of the Royal Commissioners was held at the Guildhall, Westminster, on Monday, July 4th. With the exception of Sir John Dorington and Mr. Cripps, Q.C., all the Commissioners were present. Mr. Martin, Chairman of the Water Committee of the County Borough of Croydon, was first examined. Afterwards Mr. Salter Whiter gave evidence on behalf of the Rural District Council of Croydon. Mr. T. H. Watney, Chairman of the Water Committee of the Town Council of Richmond, gave evidence on behalf of that borough and Mr. George John Courthope, J.P., for the Parliamentary Committee of the Kent County Council. After the adjournment for luncheon Dr. R. M. H. Randell gave evidence on behalf of the Beckenham Urban District Council; Lieutenant-Colonel Charles Newman Kidd, J.P., for the Dartford Urban District Council; Mr. Arthur Thomas Waring for the Dartford Rural District Council; Mr. F. H. Norman for Bromley Urban District Council; and Mr. Robert Gordon Mullen, clerk to the Bromley Rural District Council, on behalf of that body.

Mr. HOWARD MARTIN, in answer to the CHAIRMAN, said that the Corporation of Croydon had established works for the supply of water in Surrey-street, Croydon, where they had four wells in the chalk. The corporation had also a well at Addington in Surrey, a place outside the borough boundary. The corporation had expended about £150,000 on works connected with the water-supply and they were at present engaged in sinking a new well at Waddon within the borough boundary; this and other works on which they were engaged would cost about £37,000. The corporation supply the whole of the borough with water for public and

Digitized by Google

sanitary purposes; they also supply water for private and domestic purposes in the part of the borough south of the town-hall and in so much of the borough north of the town-hall as is within a distance of two miles from it. Altogether about three-fourths of the population of the borough reside in the area supplied by the corporation. The inhabitants of the other part of the borough are supplied with water for private and domestic purposes by the Lambeth Waterworks Company. The inhabitants of the district supplied by this company are extremely desirous of having their water supplied by the corporation. The corporation is prepared to provide that supply and on two occasions, in 1895 and 1897, when the London County Council promoted Bills for the acquisition by that body of some of the undertakings of the metropolitan water companies, the Croydon Corporation agreed that clauses should be inserted in the Bills to enable them to acquire from the London County Council at a price agreed upon so much of the property of the Lambeth Company as is situated within the borough of Croydon. The population of Croydon has increased very rapidly since the year 1851, when it amounted to 20,548. Thus in 1861 it was 30,663; in 1871, 56,123; in 1881, 79,615; in 1891, 102,697; and in 1897 it was estimated at 121,171. On the part of the borough of Croydon it is claimed that whatever change might be made in the present supply of water in the metropolitan area the borough should be preserved in her present rights of water-supply and that the part of the borough now supplied by the Lambeth Company should be transferred to the water area of the corporation. The district supplied by the Lambeth Company could be much better supplied from Croydon than from Lambeth and the present arrangement has many disadvantages. The Croydon Corporation had considered the question which was submitted to the Royal Commissioners—"Whether, having regard to financial consideration and to present prospective requirements as regards water-supply in the districts within the limits of supply of the metropolitan water companies, it is desirable in the interests of the ratepayers and water consumers in those districts that the undertakings of the water companies should be acquired and managed by one authority"—and in answer to this question the opinion of the corporation was as follows:—

The acquisition of the undertakings does not affect the borough of Croydon, except with regard to the small part of the undertaking of the Lambeth Water Company within the borough, and the corporation prefers therefore to limit its statements to that detail. The corporation is of opinion, however, that the question of the water-supply of the area south of the river could be efficiently and satisfactorily dealt with by placing the same in the hands of the four county authorities exercising control over that area—i.e., the County Councils of London, Surrey, and Kent, and the Council of the County Borough of Croydon, each exercising jurisdiction within their own area, and are not in favour of one authority being established for that area.

If the Commissioners decided to recommend that the undertakings should not be acquired by one or more authorities the Town Council of Croydon were of opinion that additional powers of control should be given to local authorities with regard to the water-supply within their own area, and that such control should extend to the quantity, the quality, and the efficiency of the supply.

In answer to MR. MELLOR the witness said that the objection which the inhabitants of part of Croydon had to being supplied as at present by the Lambeth Company was that they had to pay a higher price to the company for worse water.

In answer to the CHAIRMAN the witness said that the water supplied by the Lambeth Company was not so good after floods in the Thames, that the supply given by that company was not constant, and that the mains laid were not sufficiently deeply placed.

In answer to MR. DE BOCK PORTER the witness pointed out that the sum paid for water to the Lambeth Company amounted to about 50 per cent. more than that paid to the Corporation of Croydon. In the case of the water supplied by the corporation, roughly speaking, the price amounted to 5½ and in the case of the Lambeth Company to 7¾ per cent. of the rateable value. The figures arrived at were taken from an average of a number of houses of different rateable values.

Major-General SCOTT said that the corporation could insist that a constant supply of water should be given by the Lambeth Company. The witness said that the corporation had no experience of the Metropolis Water Act of 1897 and not being a lawyer he could give no opinion upon it, but he thought that the working would probably be expensive.

The CHAIRMAN said that under the Act of 1871 the people of Croydon could insist on having a constant supply of water.

With regard to control the witness said, in answer to Major-General SCOTT, that in his opinion the local authorities should have power to examine water in the reservoirs of the water companies, and Major-General Scott remarked that this was a very practical suggestion.

With regard to the complaint of the people of Croydon that they did not have a constant supply of water, the CHAIRMAN pointed out that the Act of 1897 had been in force more than a year, and it appeared that by the provisions of that Act the corporation could easily make the Lambeth Company give a constant supply of water, and that if the town council "did not trouble their heads" about Acts and never even read them it seemed to him that it was useless for them to complain to the Commissioners on a matter which they could have had put right for themselves.

MR. SALTER WHITER, on behalf of the Croydon Rural District Council, said that the district in which he was interested was thickly populated and consisted of nine parishes, more or less surrounding the borough of Croydon. The most thickly populated part of the district was situated to the north-west of Croydon, and bounded towards the north by some of the metropolitan parishes and by Wimbledon. In this district the parishes of Mitcham and Merton contained a population of 17,000, and were supplied by the Lambeth Water Company. In the early part of the year 1895, during the frost, there was almost a general blocking of the company's mains, which in some cases was possibly due to the proximity of the pipes to the surface of the ground. He had many reasons for saying that the company were very dilatory in making provisions for the emergency. Many of the houses in the district were without a proper supply, and as it is the duty of the council to see that the people have water to drink they were obliged to distribute water to the houses until the Lambeth Company had made proper arrangements. The company had refused to recoup the council for the expenses they had incurred in conveying water to the houses of the people. After the frost was over the work of repairing the damage to the mains was delayed for a very long time, and although the extent of the damage was some excuse for the delay still more expedition might have been used. Some houses did not obtain their usual supply until the middle of June, and the majority of the houses were without water for two months.

In answer to MR. DE BOCK PORTER the witness said that the inhabitants paid the water rent for the period during which they had no supply of water from the Lambeth Company. There was no question at all as to the fact that the Lambeth Company had failed to supply water. With regard to the question of the purchase of the water companies' undertakings the council were not unanimous. The opinion of the majority of the council was, however, that there should be some scheme of purchase by the local authorities and that each authority should have full power of control over its own individual supply. Should the scheme of purchase not be carried out the council were of opinion that additional powers should be given to the local authorities whose districts are within the limits of supply of the public companies. The local authorities ought to have power to examine the sources of water-supply at any time and the means and methods employed to store and to purify it. Power should also be given to local authorities to require a constant supply of water to be given by the companies. About half the water in the district was supplied by the Lambeth Company and the other half from wells. The witness thought they would be able to obtain a sufficient amount of water from wells for the supply of the whole district.

In answer to MR. RICKARDS, who appeared for some of the water companies, the witness insisted that in the year 1895 the Lambeth Water Company left the local authorities to supply the people with water as best they could.

In answer to MR. CRIPPS, the Parliamentary agent of the London County Council, the witness said that his council had not gone into the question of the merits of the Welsh scheme at all and did not think the matter of any interest to their district.

MR. T. H. WATNEY, on behalf of the Borough of Richmond, said that in the year 1877 Richmond obtained powers to supply the parish of Richmond with water. At that time the Southwark and Vauxhall Water Company were supplying them with water without Parliamentary sanction, Richmond being outside their authorised limits of

Digitized by Google

supply. The immediate cause which induced the Richmond people to wish to supply themselves with water was due to the high charges made by the Southwark and Vauxhall Company in Richmond and to the insufficient supply which they received from that company. The corporation having established their waterworks and carried them on successfully for a number of years did not desire to be attached to any scheme which might be brought forward for the supply of the metropolitan area. The reasons were as follows:—

1. On account of the purity of the water. The Richmond water, with the exception of that purchased from the company, all being derived from springs. 2. The corporation feel convinced that they will by any amalgamation have to pay at least 50 per cent. more for the water that they would consume, not taking into account that the amount now paid for the redemption of the loan is itself equal to a rate of 5d. in the £ out of the present rate of 11d. 3. The water committee hope and believe that very shortly they will have increased their local supply, so as to be enabled to meet all requirements without the assistance of the Southwark and Vauxhall Company.

At the present time, the witness said, the arrangement was that the Corporation of Richmond could have one million gallons of water a day from the Southwark and Vauxhall Company at the rate of 1s. per 1000 gallons. The corporation hoped and believed that in time they would be able to obtain sufficient water from their own wells to supply the whole of the population. They did not wish to be interfered with in any way by the London County Council and were content with the present arrangements. The water which was obtained from the Southwark and Vauxhall Company was not so good as that which came from their own wells. The Bath Committee of the Corporation of Richmond objected to have the Southwark and Vauxhall Company's water for the supply of public baths because they found it "turned green." The corporation objected to any control being exercised over their water-supply by the London County Council because they thought that they might not be strong enough under those circumstances to maintain their present position with regard to the water-supply.

In answer to Major-General SCOTT the witness said that the well which they used went into the chalk, which was reached at a depth of about 300 ft. and extended through it for a depth of about 25 ft. They had been pumping water for ten years and there was no falling off in the quantity of water which they were able to obtain from the chalk. The layer of sand above the chalk had, however, been depleted.

In answer to Mr. CRIPPS, the Parliamentary agent to the London County Council, the witness said that since they had obtained an Act of Parliament in 1877 to enable them to procure their own water-supply they had had no trouble with the Southwark and Vauxhall Company. He did not think that the London County Council would be able to manage the water undertakings as well and as economically as they were managed at present.

Mr. GEORGE JOHN COURTHOPE, J.P., Chairman of the Parliamentary Committee of the Kent County Council, said that the area of Kent affected by the inquiry of the Commissioners was supplied by the Kent Water Company, with the exception of the district of Beckenham, which was supplied by the Lambeth Company. The whole supply of the Kent Company was drawn from wells in the chalk. The company had several wells and pumping stations. The amount of water now drawn from the chalk was very considerable and the pumping had effected a marked diminution in the water of the streams and springs in the neighbourhood of the pumping stations. It had been estimated that the chalk in the district could afford a supply of 27,500,000 gallons a day, but at present rather less than 15,500,000 gallons a day were pumped. The witness thought that if the full amount of 27,500,000 gallons were pumped there would remain hardly a spring or stream of water in the whole neighbourhood. The depletion of the wells and springs by the pumping operations had already caused serious inconvenience to landowners and others in the county and they were anxious that the depletion should not increase. The witness thought that the people of Kent have the first right to the water which lies under their feet and one of their foremost principles was "Kent water for Kent." The authorities of Kent objected to large quantities of water being pumped out of Kent for the use of London and they viewed with apprehension the formation of any "water trust" with intercommunication of supply. They objected equally to any amalgamation of the water companies, as that course would undoubtedly lead to an intercommunication of supply and in the case of any pollution of the river supply the Kent water might be drawn upon for the whole of London south of the Thames and this would involve a most serious state of things for those who relied on a supply of surface water and also for the water consumers of Kent generally. Another objection to the amalgamation of the water companies was that there would probably be an equalisation of water rents, and as the rents charged by the Kent Water Company were lower than those of many of the other companies it was unreasonable that the rates charged to the water consumers of Kent should be increased whilst water can be obtained at a small expense in their own district. The witness contended, however, that although the water rents of the Kent Company were fairly reasonable when compared with those of the other metropolitan companies, yet as he understood that the cost of pumping the water in Kent was less than 2d. per 1000 gallons the company charged more than 10d. per 1000 gallons when the water was taken by meter. The witness contended that the Kent Company stood in a different position from that of all the other metropolitan companies. It was a Kent company and not a London company and should be treated as such. Should there be a "municipalisation" of the water companies the Kent undertakings should be transferred to the Kent authorities and the latter might be placed under the obligation to continue to supply the metropolitan area at present situated in the Kent Company's London district.

In answer to Mr. CRIPPS, the witness said that they wished very strongly that the London County Council should have no power over them.

Dr. REGINALD MAURICE HENRY RANDELL gave evidence on behalf of Beckenham Urban District Council. He said that the district for which he appeared had an area of 3881 acres and a population of 24,200 and that the district was supplied in part by the Kent Company but chiefly by the Lambeth Company. The part supplied by the Kent Company consisted of 413 acres and the population was 1507. The part supplied by the Lambeth Company consisted of 3468 acres and had a population of 22,719. On the question of the water-supply Beckenham had acted in cordial agreement with the other District Councils in West Kent—viz., the Bromley Urban and Rural Districts, the Sevenoaks Rural, the Erith and Dartford Urban Districts, the Bexley Urban and the Dartford Rural District Councils. The areas presided over by these councils formed the district outside the metropolitan area supplied by the Kent company. They comprised altogether an area of 148 square miles and had a population of 126,838 and a rateable value of £926,539. The part of Beckenham supplied by the Kent Company was well served, the charge for water was reasonable and, apart from the general theoretical principle that a primary necessity like water, on which the health of a district so much depends, should be in the hands of a local authority, Beckenham had no reason for desiring a change. In the part of Beckenham supplied by the Lambeth Company the question was entirely different. The Lambeth Company charged a high rate. The water obtained from the Thames had to be carried a distance of sixteen miles and lifted several times in transit. Beckenham being at the farthest distance from the source of supply is affected by every breakdown that occurs at any point between the intake of the company and that district. The inconvenience in connexion with such a breakdown is intensified and becomes a danger owing to the conduct of the Lambeth Company. For example, in the year 1893 the supply was cut off without notice and many cases were brought to the knowledge of the district council where the first intimation the householders had that there was no water was that the kitchen boiler of a would-be water consumer was red hot. Representations were made to the Lambeth Company and they promised to give notice in case of any future breakdown, the council undertaking to make the fact known in their district. Breakdowns had since occurred on no less than five occasions. No notice whatever was given to the council and the inhabitants were left to discover the absence of water for themselves. On Monday, June 21st, 1897, the water-supply failed and no notification was received from the company. On the following day (Jubilee day) the supply was very limited and on Wednesday, by request of the Lambeth Company, road watering ceased. Great inconvenience was experienced in consequence of the want of water. In reply to a strongly-worded remonstrance concerning the deficiency of supply the company refused to continue the correspondence. At the present time Beckenham is partly supplied by river water pumped from Thames Ditton, although there is an ample supply of the

Digitized by Google

purest water under Beckenham itself and this water is being pumped by the Kent Company for the supply of other districts. In the opinion of the witness the inhabitants of West Kent have the prior claim to the water in their district and are entitled to make provision for the increase in the population which they have every reason to expect. It is unfair to Kent that its streams and wells should be depleted for the supply of London.

In answer to the CHAIRMAN the witness said that the Beckenham Urban District Council strongly objected to any interference in their water-supply by the London County Council.

Lieutenant-Colonel CHARLES NEWMAN KIDD, J.P., gave evidence on behalf of the Dartford Urban District Council. He said that he had been a member of the Dartford Local Board for more than twenty-four years and of the Dartford Urban District Council for over four years. He entirely objected to the transfer of the Kent water to the London County Council and was of opinion that the Kent Company stood in a different position from that of any other metropolitan company. It was essentially a Kent company, not a London company, and it should be treated as such. There are three wells at Dartford; the amount of water drawn from the chalk there is very considerable and has a marked effect on the springs and streams in the neighbourhood of the pumping-station. The depletion of the wells by pumping operations had caused serious inconvenience to land-owners and others and they were very anxious that the depletion of water should not be increased. Originally the waterworks at Dartford were in the hands of the local authority and they sold them to the Kent Company and the Dartford authorities have since much regretted that they sold their undertakings. The stream near the new pumping-station at Wilmington had almost disappeared in consequence of the pumping from a well which had lately been sunk there.

Mr. ARTHUR THOMAS WARING, on behalf of the Dartford Rural District Council, said that they were quite satisfied with the present supply of water and in their opinion the Kent local authorities should have the control of the water which lies under their feet. There were three wells and three pumping arrangements at Dartford and the depletion of wells and springs both in the Dartford and the Beckenham districts had already caused serious inconvenience. The population of Dartford Union had increased from 53,435 in the year 1881 to 68,702 in 1891, and it was certain that year by year they would want more water for the supply of their district. For this reason the Dartford Rural District Council was in entire accord with the other Kent local authorities in objecting to large quantities of water being pumped out of Kent for the use of the metropolis and they viewed with apprehension the formation of any water trust. The witness said that at the present time the River Cray contained only about one-fourth or one-fifth as much water as it formerly had and in his opinion the amount of water flowing down this stream has been materially affected by the pumping at the Orpington station of the Kent Company.

Mr. F. H. NORMAN, on behalf of the Bromley Urban District Council, said that the population of Bromley was rapidly increasing. In the year 1871 it was 10,673 and at the present time it was estimated at 26,000. The council which he represented, with the exception of two points of detail, were content with the present supply given by the Kent Company. The exceptions were: (1) the absence of a constant supply in various parts of the district; and (2) the unfair terms imposed upon the council for water used for public purposes, inasmuch as small trade consumers were charged as much as 2½ per cent. less than the amount charged to the council for sanitary purposes. The Bromley Urban District Council were unanimously of opinion that the London County Council is not the proper authority to control the water-supply of their district, and that should any transfer of the existing undertakings of the Kent Company be made the various local authorities in Kent outside the London area should be entrusted with the management of their own water-supply, and that the Kent local authorities are primarily entitled to deal with the Kent water, or, as an alternative policy, the Kent County Council should be constituted the water authority with respect to the Kent area.

Mr. ROBERT GORDON MULLEN, clerk to the Bromley Rural District Council, said that the Kent Company had always supplied water of a high standard of purity and upon fairly liberal terms, and the authorities outside the London County Council area in West Kent were unanimous that should Parliament "in its wisdom" decide that the control of the water-supply should be transferred from the existing companies to public authorities, the London County Council ought not to be allowed to control the Kent water but that the control should be vested in the Kent authorities either as a "water trust" composed of representatives of the various local authorities, or that the control of the water should be given entirely to the Kent County Council for their joint benefit.

In answer to Mr. CRIPPS the witness said that he was convinced that in the interests of Kent it would be best if matters were left as they are.

The next sitting of the Commissioners will take place on Monday, July 11th, at the Guildhall, Westminster.

THE COMPLIMENTARY DINNER TO DR. PLAYFAIR.

THIS dinner (adjourned from June 8th) was held at th Grand Hotel on Monday, July 4th. Lord Lister occupied the chair. Nearly a hundred persons were present, among them being Sir Samuel Wilks, Bart., Sir Joseph Fayrer, Bart., Sir James Kitson, Bart., M.P., Sir William Priestley, M.P., Sir Dyce Duckworth, Sir Felix Semon, Sir Walter Foster, M.P., Dr. Farquharson, M.P., Bishop Barry, Rev. Dr. Robertson (Principal, King's College), Rev. Dr. Wace, Dr. Cullingworth, Dr. Constantine Holman, Dr. Buzzard, Dr. Maclagan, Dr. Donald Hood, Dr. Blandford, Dr. Kingston Fowler, Dr. Handfield-Jones, Dr. Amand Routh, Surgeon-Colonel W. H. Roberts, Dr. Octavius Jepson, Dr. Bezly Thorne, Mr. Malcolm Morris, Dr. Thomas Walker (Peterborough), Dr. Nicholson (Brighton), Dr. Murphy (Sunderland), Dr. Marriott Cooke, Dr. Fletcher Beach, the staff of King's College and Hospital, and a considerable number of former resident accoucheurs. Letters of regret were received from Viscount Dillon (chairman of the hospital), Sir William Broadbent, Bart., Sir William Turner and Professor Simpson (Edinburgh), and many others. The proceedings were throughout characterised by the greatest cordiality, the speeches of the Chairman and Dr. Playfair meeting with repeated rounds of applause.

The toast of "The Queen" having been duly honoured,

Lord LISTER, in proposing that of "The Guest of the Evening," referred to their first acquaintance forty-four years ago when Dr. Playfair was dresser under Mr. Syme during his own house-surgeoncy under that great surgeon. He briefly sketched Dr. Playfair's subsequent career, first as a surgeon in the East India Company's service and afterwards as a specialist in the department in which he had been so greatly distinguished. He illustrated Dr. Playfair's clear-sightedness and skill by his early recognition of the importance of antiseptic principles in the days of carbolic putty which he had employed with such success as entirely to abolish sinus of the mamma in his own practice. Dr. Playfair's work on midwifery was at once recognised as of very great value and stamped him as a high authority in his subject. Referring to the trial in which Dr. Playfair was recently concerned Lord Lister spoke of it as a grievous travesty of justice which had not in the slightest degree diminished the esteem in which Dr. Playfair had been previously held. Dr. Playfair's kindness of heart and straightforwardness, together with his professional distinction, explained his great popularity with those who served under him, and this was strikingly illustrated by an illuminated address presented to him that evening by nearly 50 former resident accoucheurs in King's College Hospital. All present, whether former students, former colleagues, or others, rejoiced in this opportunity of doing honour to Dr. Playfair, and united in the cordial wish that his retirement from hospital and professorial duty might be followed by many years of health, prosperity and happiness.

Dr. PLAYFAIR expressed his gratitude to the gentlemen present for the distinguished honour they had done him by being present in such numbers to wish him well. After commenting on his connexion with King's College he said that Lord Lister having spoken so kindly on an incident in his career which certainly could not be regarded as a pleasant one—viz., the *cause célèbre* in which he had the misfortune to be the defendant—he felt that he could not avoid saying a few words with regard to it. Up to this time

Digitized by Google

he had made it a rule never to speak of this matter in public and as little possible in private, and had it not been spoken of he should not now have deviated from that rule. On the conduct of that trial he should make no remark lest he should be tempted to say that which had better be left unsaid. The sensation which it caused was mainly due to the question of professional confidence so ingeniously raised by the talented counsel who represented the plaintiff—a question used by him as a sort of forensic red herring in order to divert attention from the other and more important matters; of that he made no complaint, since it was often the duty of counsel to make white appear black and black appear white. The circumstances of the case were so entirely of a domestic and family character as altogether to remove it from the category of ordinary professional attendances, so much so that it had never occurred to him, to his lawyers, or to his counsel that any professional question could be connected with it. All he need say on this point was that in very painful, very exceptional, and difficult circumstances he had acted as he thought a gentleman, a man of honour, and the head of a family who respected the sanctity of family life ought to have acted, and he sincerely hoped that under similar conditions he would have the moral courage to do exactly the same thing again. Amongst the innumerable expressions of confidence, goodwill, and affection which he had received from old patients, friends, and pupils there was none which gratified him so much as a letter he had received from a man whose high moral rectitude and absolute purity of principle were universally acknowledged. Mr. Gladstone, to whom he was practically unknown, had done him the signal honour to write him a letter not marked "private," so that he was justified in quoting it, in which he said: "Having most carefully studied all the evidence in this trial I can come to no other conclusion than that you have done neither more nor less than your duty." That verdict from such a master of ethics carried, to his mind, immensely more weight than the hysterical and sentimental pronouncement of such a judge and such a jury. Dr. Playfair concluded by referring to the careers of many of his old friends and fellow students who were present and to his long friendship with Lord Lister.

Other toasts were "King's College and its Hospital," proposed by Bishop BARRY and responded to by the Rev. Dr. ROBERTSON and Dr. DUFFIN, and "The Chairman," proposed by Sir SAMUEL WILKS. The evening's proceedings were much enlivened with songs by Mr. William Nicoll.

A UNIVERSITY FOR BIRMINGHAM.

THE prospect of a university for the great central town of the Midlands has been kept steadily in view for some years past. It is now within reach of accomplishment. A large and representative meeting was held in the Council House at Birmingham on July 1st, under the presidency of the LORD MAYOR of Birmingham (Mr. Councillor Beale), amid much enthusiasm. The claims of the city and surrounding district to this distinction were warmly advocated and a material impetus was given to the project by the announcement that though no public appeal had yet been made the promises of subscriptions amounted to £95,580, the estimate for the total completion being put at £250,000. At the meeting the advantages of a university for the particular district were set forth from many points of view—the manufacturer, the professor, the statesman, and the bishop alike urging the necessity and merits of such an undertaking.

Mr. G. H. KENRICK, the vice-president of the School Board—a generous contributor of £10,000 to the fund—pointed out that the industries special to the locality were inseparable from the association with science and scientific research and strongly required in their progress the recognition of this teaching.

Professor TILDEN also compared the technical teaching of England with that of the continent and some American universities, giving illustrations from various universities.

The Right Hon. JOSEPH CHAMBERLAIN referred to the advance made in the cause of education in Birmingham during the last thirty years. He dwelt upon the importance and value to public and social life of a school of learning and knowledge in the midst of this great manufacturing centre. A comparison was drawn of the number of universities to the population in Scotland and some continental countries and emphasis was laid upon the local needs for local teaching.

The Bishop of HEREFORD (Dr. Perceval), in expressing his approval of the scheme, stated his opinion that the circumstances of the time made it important that they should do all they could to establish these intellectual centres in the great cities. More and more we were becoming a commercial and industrial democracy.

Dr. C. T. WILLIAMS, the representative of the Royal College of Physicians of London upon the Council of Mason University College, spoke of the difficulty which medical students, even London students, experienced in getting degrees, many having to go to Scotland for them. He predicted that the new university would be one of the most successful in England.

The interest of the medical profession locally undoubtedly lies in the greater facility which the university would afford for the obtaining of degrees. As a rule, in provincial schools it is not so much the want of ability as the lack of means which prevents the acquisition of a degree; it is thus felt that the success of the scheme would yield considerable advantages to the medical student in the lessening of cost, the non-necessity of going from home, and the attachment to the local school with which such exceptional clinical opportunities are allied. The saving of trouble and expense in crowning the curriculum by a degree locally obtained would materially strengthen the medical school. Whatever the comparison with the aims and methods of the older universities may evoke it is unquestionable that for the higher intellectual development, for the opening ground for original research, for the retention of local talent, by adequate acknowledgment, the proposed university would add to the culture and material progress of the city and vast manufacturing population around.

METROPOLITAN HOSPITAL SUNDAY FUND.

THE following were among the principal amounts received at the Mansion House in aid of this Fund during the past ten days. The total sum up to Wednesday afternoon amounted to about £34,000.

	£	s.	d.
St. Michael, Chester-square (with additions)	1283	0	0
St. Peter, Cranley-gardens	501	3	7
St. Jude, South Kensington	621	8	0
St. Mary, Bryanston-square	250	0	0

BERLIN MEDICAL CLUB.—We are informed that foreign medical men are eligible for membership of the newly-established Berlin Medical Club without payment of entrance fee (*können sich frei einführen lassen*) and that foreign medical visitors to Berlin may be admitted to temporary membership. The club is situated in the Linden-gallerie, Berlin, W.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Liverpool Urban District.—The population of this city was estimated in 1897 to be 644,129, but Dr. Hope considers that this figure is considerably under the actual population, and he tells us that towards the close of the last intercensal period there was an error of not less than 100,000 in the Registrar-General's estimate of the population. The mean birth-rate of the city for the last ten years has been as much as 34·5, the rates for the several wards ranging during 1897 from 46·9 to 19·6 per 1000, and, curiously enough, the rate was higher in the older parts of the city than in the rapidly-growing suburbs. The birth-rate has during the last decade shown no tendency towards diminution. As regards deaths the rate for 1897 was 23·4 per 1000, the ward rates varying from 39·8 to 10·2 per 1000. Typhus fever, though gradually disappearing from Liverpool, still exerts some influence there and last year there were 158 cases with 23 deaths. Of illness from ice-cream we have heard much in London of late, and Dr. Hope records an outbreak in which 27 cases of enteric fever occurring in children were traced to an Italian ice-cream vendor, in whose house, at the time when the children were apparently infected, there was a case of enteric fever. In Liverpool ice-cream vendors must have their premises registered and during 1897 48 persons made application for such registration. There were no less than 1039 deaths from zymotic diarrhœa or acute gastro-enteritis in the six weeks ending Sept. 4th, and Dr. Hope endeavours to show the connexion which obtains between diarrhœal mortality and warmth and dryness, illustrating his point by the rainfall of the last 20 years. He regards the flushing of street surfaces, of drains, and of sewers as the main indications of the conclusions he arrives at. In connexion with the question of sanitary administration it is of interest to note that, counting 2 temporary assistants, there are in all 115 persons on the sanitary staff. The inspectors of meat and animals are butchers by trade, those of fish and fruit fishmongers. To the subject of tuberculosis Dr. Hope devotes considerable space in his report, and in tabular form he shows the marked diminution which has taken place in the mortality from this disease in Liverpool since 1866. In connexion with the infection of milk the following table of samples tested is of interest, and it tends to show, in so far at least as these figures go, that the conditions *quâ* tuberculosis obtaining in the town shippons of Liverpool are better than those found in the country shippons of the surrounding districts. It will be noted that the total number of samples collected from the country is but small.

—	Total.	Infected.	Per cent.
Town shippons	228	12	5·2
Country shippons	67	9	13·4

As regards insanitary property Dr. Hope reports that of the 240 houses included in the thirteenth presentment most had by the end of 1896 been dealt with by the Insanitary Property Committee, while in January, 1897, the medical officer of health presented to the grand jury a report relating to 890 houses, and after taking evidence and inspecting the property the jury ordered the houses to be demolished under the provisions of the Liverpool Sanitary Amendment Act, 1864.

Manchester Port District.—The port of Manchester is what is known as a "temporary" port—that is to say, it is formed for a definite period only, at the end of which time it may either be converted into a "permanent" port or pursue its temporary existence for another period. The limits of jurisdiction of the sanitary authority are extensive and embrace the whole of the Manchester Ship Canal. Between April and December, 1897, there were 790 vessels inspected in the several parts of the port, and on board 86 of these defects were discovered. As to hospital accommodation Dr. J. H. Crocker reports that arrangements have been made by which cases of small-pox can be removed to the Mode Wheel Hospital of the Salford sanitary authority and cases of other infectious disease to the Ladywell Sanatorium.

Digitized by Google

Regulations under Section 125 of the Public Health Act, 1875, are now before the Local Government Board and it would seem that the Manchester Port Sanitary Authority will soon be in working order.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6575 births and 3203 deaths were registered during the week ending July 2nd. The annual rate of mortality in these towns, which had been 14·7 and 15·1 per 1000 in the two preceding weeks, declined again last week to 14·9. In London the rate was 14·5 per 1000, while it averaged 15·1 in the thirty-two provincial towns. The lowest rates in these towns were 9·0 in Preston, 10·3 in Norwich, 10·6 in Cardiff, and 10·9 in Croydon; the highest rates were 18·6 in Gateshead, 19·0 in Wolverhampton, 20·8 in Newcastle-upon-Tyne, and 22·8 in Sunderland. The 3203 deaths included 342 which were referred to the principal zymotic diseases, against 342 and 301 in the two preceding weeks; of these, 94 resulted from whooping-cough, 77 from measles, 59 from diarrhœa, 55 from diphtheria, 29 from "fever" (principally enteric), 27 from scarlet fever, and 1 from small-pox. No death from any of these diseases was recorded last week in Derby or in Huddersfield; in the other towns they caused the lowest death-rates in Brighton, Blackburn, and Bradford, and the highest rates in Norwich, Newcastle-upon-Tyne, Salford, and Plymouth. The greatest mortality from measles occurred in Plymouth; and from whooping-cough in West Ham, Salford, Gateshead, and Newcastle-upon-Tyne. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 55 deaths from diphtheria included 28 in London, 4 in Cardiff, 4 in Leeds, and 3 in Bristol. One fatal case of small-pox was recorded in Newcastle-upon-Tyne, but not one in any other of the thirty-three large towns; and no small-pox patients were under treatment during last week in any of the Metropolitan Asylum Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital was 2205 on Saturday last, the 2nd inst., against 2194 and 2238 at the end of the two preceding weeks; 204 new cases were admitted during the week, against 206, 230, and 231 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 185 and 171 in the two preceding weeks, further declined to 162 last week, and were 27 below the corrected average. The causes of 38, or 1·2 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Nottingham, Bradford, Leeds, and in fourteen other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Bristol, Leicester, and Huddersfield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the four preceding weeks from 23·0 to 19·5 per 1000, rose again to 21·1 during the week ending July 2nd, and exceeded by as much as 6·2 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·6 in Perth and 17·7 in Leith to 23·4 in Dundee and 25·5 in Paisley. The 635 deaths in these towns included 41 from measles, 35 from whooping-cough, 30 from diarrhœa, 5 from scarlet fever, 4 from diphtheria, and 4 from "fever." In all, 119 deaths resulted from these principal zymotic diseases, against 92 and 102 in the two preceding weeks. These 119 deaths were equal to an annual rate of 3·9 per 1000, which was 2·3 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 32 and 37 in the two preceding weeks, further rose to 41 last week, and included 13 in Edinburgh, 11 in Glasgow, 11 in Dundee, and 5 in Paisley. The deaths from whooping-cough, which had been 22 and 27 in the two preceding weeks, further rose to 35 last week, of which 19 occurred in Glasgow, 5 in Edinburgh, and 5 in Aberdeen. The 5 fatal cases of scarlet fever were within one of the number in the preceding week, and the 4 deaths referred to different forms of "fever" corresponded with the number recorded in the preceding week. Of the 4 fatal cases of diphtheria 2 occurred in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 108 and 93 in the two preceding weeks, rose again to 101 last week, and were 15 above the number in the corresponding period of last year. The causes of 41, or more than 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 21·9 and 22·8 per 1000 in the two preceding weeks, declined again to 21·8 during the week ending July 2nd. During the thirteen weeks of the quarter ending on Saturday last the death-rate in the city averaged 23·5 per 1000, the rate during the same period being 16·4 in London and 19·7 in Edinburgh. The 146 deaths registered in Dublin during the week under notice showed a decline of 7 from the number in the preceding week, and included 11 which were referred to the principal zymotic diseases, against 6 and 8 in the two preceding weeks; of these, 4 resulted from "fever," 3 from diarrhœa, 2 from scarlet fever, 1 from diphtheria, and 1 from whooping-cough, but not one either from measles or small-pox. These 11 deaths were equal to an annual rate of 1·6 per 1000, the zymotic death-rate during the same period being 1·9 in London and 4·6 in Edinburgh. The deaths referred to different forms of "fever," which had been 4 and 1 in the two preceding weeks, rose again to 4 last week. The two deaths from scarlet-fever exceeded the number recorded in any recent week, while the mortality from diphtheria and whooping-cough showed a decline. The 146 deaths in Dublin last week included 29 of infants under one year of age, and 21 of persons aged upwards of sixty years; the deaths of infants showed an increase, while those of elderly persons were considerably below the number recorded in any recent week. Six inquest cases and 3 deaths from violence were registered; and 63, or more than one-third, of the deaths occurred in public institutions. The causes of 6, or more than 4 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

NAVAL MEDICAL SERVICE.

SURGEON HORATIO W. A. COWAN has been appointed to the *Howe*.

ARMY MEDICAL STAFF.

Brigade-Surgeon-Lieutenant-Colonel Robert de la Cour Corbett, D.S.O., to be Surgeon-Colonel, vice J. Williamson, deceased. The under-mentioned Surgeon-Lieutenant-Colonels to be Brigade-Surgeon-Lieutenant-Colonels: John C. Dorman, vice J. H. Moore, promoted, and George H. Le Mottée, vice R. de la C. Corbett. Surgeon-Colonel T. O'Farrell, Home District, goes to Egypt as P.M.O., vice Surgeon-Major-General Muir.

VOLUNTEER CORPS.

Artillery: 2nd Middlesex: Surgeon-Captain A. H. Robinson to be Surgeon-Major. 1st Orkney: George Robert Clair Russell to be Surgeon-Lieutenant. 2nd Hampshire (Southern Division, Royal Artillery): Surgeon-Major G. G. Sparrow to be Surgeon-Lieutenant-Colonel. *Rifle:* 1st Volunteer Battalion the Buffs (East Kent Regiment): Herbert Stedman Oliver to be Surgeon-Lieutenant. 2nd Volunteer Battalion the Gloucestershire Regiment: Surgeon-Lieutenant P. T. Lunn to be Surgeon-Captain. 2nd Volunteer Battalion the South Staffordshire Regiment: Captain James Scott Wilson, formerly Surgeon, resigns his commission and is appointed Surgeon-Captain. 3rd Glamorgan: Surgeon-Lieutenant A. L. Jones to be Surgeon-Captain. 1st Volunteer Battalion Princess Charlotte of Wales's (Royal Berkshire Regiment): William Gratwicke Heasman to be Surgeon-Lieutenant. 1st Volunteer Battalion the Buffs (East Kent Regiment): Edward Arthur Crampton Baylor to be Surgeon-Lieutenant. 2nd Volunteer Battalion the Lancashire Fusiliers: Surgeon-Major C. W. Thorp to be Surgeon-Lieutenant-Colonel. 1st (Cumberland) Volunteer Battalion the Border Regiment: Samuel Maclean to be Surgeon-Lieutenant. 2nd Volunteer Battalion the Highland Light Infantry: William Fraser Macdonald to be Surgeon-Lieutenant. 1st (Inverness-shire the Highland) Volunteer Battalion the Queen's Own Cameron

Digitized by Google

Highlanders: Surgeon-Lieutenant J. Murray resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the battalion on his retirement.

VOLUNTEER INFANTRY BRIGADE.

East London: Surgeon-Lieutenant-Colonel W. R. Smith, 1st London Volunteer Rifle Corps, to be Brigade-Surgeon-Lieutenant-Colonel, on appointment as Senior Medical Officer to the Brigade.

THE SPANISH-AMERICAN WAR.

The number, rapid movement, and great gravity of the events which have taken place in the short time which has elapsed since the publication of THE LANCET of July 2nd have been of the most striking and dramatic character. There is no need to make any attempt to chronicle them, for this has been already done in the daily press and their sensational interest has compelled public attention. One day it is General Shafter's force besieging Santiago that is in a most difficult position and giving rise to no little anxiety in the States, and the next we hear of the annihilation of Admiral Cervera's fleet in its attempted escape from Santiago and the whole situation is completely changed. The Spanish war policy is incomprehensible as well as most unfortunate. Her naval losses have been unparalleled, but there is nothing to be learned from all the fighting. Turning to medical matters we may say that the Surgeon-General of the United States Army has had a conference with the Surgeon-General of the Navy and preparations have been hurriedly pushed forward to afford medical aid to General Shafter's force. The hospital ships *Solace* and *Relief* have left for Santiago. The latter vessel is admirably fitted out and is said to have accommodation for 500 men.

DEATHS IN THE SERVICES.

Brigade-Surgeon-Colonel Williamson, at Lucknow, in his fifty-fifth year. The deceased officer entered the service in 1867, was stationed at Paisley and Gosport, and subsequently went to Abednegar, India, where he remained for a number of years. On his return home he was for five years stationed at York and returning again to India took part in the first Ashantee expedition (medal). He ultimately became Brigade-Surgeon and principal medical officer of Lucknow.

Surgeon-Captain Archibald William Forbes Russell, I.M.S., suddenly from sunstroke on June 21st at Bareilly, Bengal. He joined the service in 1894, and was promoted surgeon-captain last year. The deceased officer was in his thirtieth year.

THE ROYAL MILITARY TOURNAMENT.

A statement of the finances of the Royal Military Tournament recently held at the Royal Agricultural Hall has been issued. The receipts amounted to £28,992 3*s.* 7½*d.* They have been allocated in the following way: Working expenses, £16,393 10*s.* 9½*d.*; expenses of regimental and district tournaments to be held in spring, 1899, £1200; placed to reserve, £500; handed over to Commander-in-Chief for charity, £10,500; balance to meet contingencies, £398 12*s.* 10*d.*

The Queen has appointed Surgeon-Major-General William Roe Hooper, C.S.I., to be a Knight of Grace of the Order of the Hospital of St. John of Jerusalem in England.

MANCHESTER THERAPEUTICAL SOCIETY. — The annual general meeting of this society was held in the Owens College on May 29th, Dr. Leech, the President, being in the chair. The report of the committee, recording the work of the session and expressing the opinion that the inaugural session gave very satisfactory promise for the future of the society, was read and adopted. The following office-bearers were elected for the session 1898-99:—President: Professor D. J. Leech, M.D. Lond., D.Sc. Vict., F.R.C.P. Lond. Vice-Presidents: Professor J. Dreschfeld and Professor J. Dixon Mann. Hon. Treasurer: Dr. R. T. Williamson. Hon. Secretary: Dr. R. B. Wild. Committee: Dr. A. Brown, Dr. F. J. H. Coutts, Dr. A. Hopkinson, Dr. T. N. Kelynack, Dr. J. E. Platt, and Dr. A. T. Wilkinson. There was an exhibition of specimens of the new pharmacopœial drugs and those preparations which have been materially altered and Dr. Leech made a communication dealing with the new drugs introduced and pointed out the nature and importance of the changes which have been made.

"Audi alteram partem."

ARSENIC IN WOOL.

To the Editors of THE LANCET.

SIRS,—Can you spare space in your valuable journal to ventilate the question of disadvantage or injury likely to arise or not from woollen apparel and other goods containing traces of arsenic? In Sweden there is a law against the sale of material containing arsenic in any way over a minute trace. Thus yarn is not allowed to be sold in that country if it contains 0·0009 per cent. of arsenic, or 20 cwt. of yarn may contain up to 9 grammes of arsenic, but if it contains more it will be condemned and not allowed to be sold. It is known that the Swedish Government have condemned a heavy carpet because it contained one-thousandth part of a grain of arsenic in 16 square inches—that is, 1 gr. (possibly in a completely non-volatile form) in a piece of carpet 10 ft. square. This Swedish law is a source of great trouble and annoyance to our manufacturers and merchants who do business in Sweden in the wool branches of the textile trade.

I believe it is nearly if not quite impossible to buy any sheep's wool (home or foreign grown) which does not contain arsenic in larger quantity than that allowed by the Swedish Government. This arises from the fact that all sheep-growers are obliged at certain seasons to dip their sheep in a special chemical preparation to keep the animals healthy and in good order, and it is admitted that all effective sheep dips contain arsenic. Messrs. Cooper and Nephew of Berkhampstead, large manufacturers of arsenical sheep dip, state that they supply dip sufficient each year for one-fourth the sheep in the entire world and they have proved by experience that their dip improves the fleece, and I understand that it is their opinion that one-half the woollen fabrics worn in England are made with Cooper dipped (that is, arsenical dipped) wools. The arsenic from the dip clings so tenaciously to the wool fibre that even the two or three scourings with hot water, soap, and alkali, together with the various other treatments and manipulations of carding, combing, spinning, dyeing, and weaving, which the wool or yarn goes through before it becomes finished cloth, fail to destroy or get rid of the drug. It has been suggested to me that some of the readers of THE LANCET may be in a position and willing to help the home trade by giving information as to the injury or otherwise likely to arise from materials made from the wool treated as above named, and as to the maximum quantity of arsenic which might be allowed without injury to health in a given weight or size of cloth. Such information would, I think, be very valuable to all spinners and manufacturers engaged in the wool branches of the textile trades. I think it is as well to add that the Swedish way of analysing for arsenic is described in the *Chemische Zeitung* of 1892, page 420.

So far I have in a sense appealed to your readers only, but I am in hopes that you, Sirs, may also be induced to favour all interested in the matter with your opinion, which I am sure will be of considerable value. Anticipating your kindness in inserting this letter, I now thank you very much.

I am, Sirs, yours faithfully,

JOHN H. PEARSE,
President, Kidderminster Chamber of Commerce.

Kidderminster, July 2nd, 1898.

THE HABITUAL DRUNKARDS ACT.

To the Editors of THE LANCET.

SIRS,—On April 25th last a new Habitual Drunkards Act was introduced in the House of Commons. According to the provisions of this Bill only habitual drunkards who have committed a criminal offence can be received for confinement and suitable treatment during a period not exceeding two years into State asylums or into licensed private asylums. Dr. Heywood Smith very properly observes in THE LANCET of May 21st that there are many non-criminal habitual drunkards who, in common with other lunatics, should be confined for their own good and for the good of society. If, therefore, every habitual drunkard or

Digitized by Google

person suffering from chronic alcoholism be regarded as a patient, such habitual drunkard, whether he has committed a slight or a serious criminal offence or not, should equally be treated as a patient. Now as these alcoholists cannot be placed under a suitable *régime* in a lunatic asylum, and, moreover, as the other patients in the lunatic asylum suffer in many ways from intercourse with alcoholists, it becomes the duty of the State to construct separate asylums in which habitual drunkards—i.e., persons suffering from chronic alcoholism—should be confined for a sufficiently long period—let us say two years—and should be properly treated and finally discharged as cured or should be transferred to a lunatic asylum for permanent care and treatment. We will leave out of this discussion the point whether the State should to a certain extent be made liable for the maintenance of families of habitual drunkards or be charged with the administration of the property of habitual drunkards during the period of detention. The State must, however, in the end adopt the only admissible standpoint—namely, that of humanity and science. A habitual drunkard suffers from brain disease and, in common with other lunatics, must be treated as a patient. Now, a patient recognised as insane does not require to have committed a criminal offence in order to qualify for reception into a lunatic asylum and thereby to participate in the care and treatment of the asylum authorities. Why, therefore, should the case of a habitual drunkard who also suffers from brain disease be regarded in a different light? The Bill introduced on April 25th last can only become a complete success and be recognised as an important advance in scientific legislation if it ceases to be confined to the cases of criminal habitual drunkards and is extended to the cases of all habitual drunkards, being persons respectively afflicted with a psychical defect. In that way alone the final ethical object of the Habitual Drunkards Act can be attained, which should consist in diminishing the total number of individuals lost to the State through immoderate use of alcohol and in restoring a very great number of habitual drunkards to their respective occupations—that is, by curing them.

I am, Sirs, yours faithfully,

DIRECTOR SCHLANGENHAUSEN.

Velden, Austria, June 8th, 1898.

THE BRAVERY OF SURGEON-LIEUTENANT HUGO.

To the Editors of THE LANCET.

SIRS,—Commenting on your report of the speech made by Surgeon-Major-General Jameson at the annual dinner of the Indian Medical Service, in which, amongst other important matters, he refers to the heroic action of Surgeon-Lieutenant Hugo, who saved the life of a brother officer at the imminent risk of sacrificing his own, it must occur to all loyal medicals that such a service should not go without its reward, and I feel sure that there are those medical Members in the House of Commons (alas! few though they be) who, if approached, would gladly bring this matter prominently to the notice of the House and so be the means of assisting the officer to obtain that which alone he cannot—the V.C. decoration, which his commanding officer has said he so richly deserves.

I am, Sirs, yours faithfully,

Shrewsbury, July 4th, 1898. ED. CURETON.

COMPENSATION IN AORTIC REGURGITATION

To the Editors of THE LANCET.

SIRS,—The measurements I have made of the last tracing taken on May 27th of my case of aortic regurgitation have brought to light a source of error in the former tracings which must at once be corrected. Carefully as the earlier ones were taken, so that I thought there was no possibility of mistake, I am now convinced that the earlier tracings are of a reversed type and that the measurements of duration of systole in the later tracing are much more near the normal. The later measurements show: duration of systole 0·36 sec., duration of diastole 0·56 sec., heart radial delay 0·20 sec., and pulse rate 0·69 per minute.

While, therefore, conclusively showing that in this case of pure aortic regurgitation there is certainly no diminution of the heart radial interval I must withdraw the evidence I have set forth as to compensation by increased persistence of systole. It is true that the systole is slightly prolonged for the pulse-rate in question, but the point I wished to emphasise is not proven and has to be further investigated. The patient, a young man, aged thirty-six years, is now feeling quite well and is able to go fly-fishing and to play lawn tennis, &c., but the nature of the beneficial compensation probably does not lie chiefly in a prolongation of the cardiac systolic time, seeing that the prolongation is so slight.

I am, Sirs, yours faithfully,

Hereford, July 2nd, 1898. PAUL M. CHAPMAN.

THE LATE DR. BLUNT.

To the Editors of THE LANCET.

SIRS,—There is a slight error in your obituary notice in THE LANCET of June 25th of my old friend the late Dr. Blunt of Birmingham which it may be well, in memory of old associations, to correct. You say that he was never connected with any of the hospitals or public institutions of the town. For one summer session—I think it was in 1860—Dr. Blunt filled the chair of Forensic Medicine in Queen's College, and for a still shorter time he held the office of Dean of Faculty in that institution. I was his colleague at the time as a Professor in the College and followed him as Dean. It was a time of storm and stress in the history of that institution, for which Dr. Blunt was by his tone of mind not well adapted. Had he been able to retain his connexion with the College its subsequent history might have been very different. Unless, too, my memory plays me false Dr. Blunt was, if not the editor, at least the leading spirit, in the conduct of the *Midland Quarterly Journal of Medical Science*, which had a brief but not an inglorious career, and in which he was largely associated with another old colleague of mine, the late Dr. Heslop, whose memory is, I have no doubt, still cherished by many in the Midlands.

I am, Sirs, yours faithfully,

Gloucester. FRANCIS T. BOND, M.D. Lond.

"THE ALLEGED DEARTH OF QUALIFIED ASSISTANTS."

To the Editors of THE LANCET.

SIRS,—Allow me to attempt to depict the reverse side of the picture. In the first place, let me explain that after serving as medical officer and house surgeon in several institutions I took an assistancy in the country obtained by the very simple means of giving my name to a wholesale house of druggists. I was offered, and accepted, the salary of £80 (indoors). I was treated in every way as one of the family, was allowed a free hand with my patients, did a share only of the midwifery, dispensing, book-keeping, &c., and lived far better than I have ever been in a position to live since. I then took a small practice of my own for three years and was at the end of that time recalled by my former employer as partner. During my assistancy my employer's expenses were somewhat as follows: horses, £100; two grooms, £100; my own salary and board, £120; drug bill, £50; rent, £45; rent of surgery, £10; making a total of £425. His income might be averaged at £700 and he was expected to subscribe liberally to everything. I had absolutely no necessary expenses except clothing. Who was in the better position at the time—my employer with a reduced income of £275, on which to maintain a wife and family, two servants, &c., or myself with a fixed salary and no one to maintain? Of course, the thing could not have been done without private means and yet one man alone could not possibly have done the work. Then take my present position. I am in practice and in receipt of an income of about £400, to earn which I work practically night and day. I pay a rent of £35, keep two horses and a groom, and have a drug bill of about £40. I never get a holiday and want an assistant badly, but how on earth is he to be paid? Possibly the practice might increase to £600, but there would be extra horses necessary in a wide country district as well as the assistant's salary.

"An Assistant" writing on June 29th must be either a wit or an epicure. Caterpillars cooked among vegetables I have seen at the best houses and are at times quite unavoidable; the presence of "flies in beer" proves, at all events,

Digitized by Google

the presence of the beer, a luxury which many of us struggling practitioners cannot allow ourselves. "M.D., M.Ch." suggests that by offering an unfurnished house the advertiser requires "a man who has been an assistant before and will always continue to be an assistant." That appears to me to be a statement requiring proof, and, even if proved, what harm is there in it? Are there not many who will always be assistants either from want of means or from knowing when they are well off? I shall be glad if the writers will in a future issue put down in black and white what they consider to be the average income and expenses of a country practitioner and what they think an assistant should receive.

I am afraid that many have yet to learn by bitter experience that even good qualifications may not necessarily find a ready market in the medical world and that the practice of their profession entails a life of hardship, a scanty income, constant harass, and too often but little gratitude. I am not complaining of my lot. I am simply convinced that a preliminary apprenticeship would deter many an ardent young spirit from entering the ranks of our overcrowded profession. I have never advertised for an assistant nor do I at present mean to do so simply because I cannot afford it. I consider that "the labourer is worthy of his hire," but I also believe that the employer, if he works, should receive a greater remuneration than the employed; his is the responsibility, his the mental anxiety, and his the necessity for keeping up a position. It is high time that not only assistants but also the public should be made aware of what we have to live on and how difficult it is for the only man in a parish who knows no half-holiday, no evenings off, and very few Sundays, to make both ends meet.

I am, Sirs, yours faithfully,

July 4th, 1898. PRACTITIONER.

THE SANITARY INSTITUTIONS OF MADRID.

(FROM A SPECIAL CORRESPONDENT.)

THERE are several institutions in Madrid connected with public health services which have been organised on modern principles and which show that the cause of sanitary reform has of late years made notable progress in Spain. Thus there is the Provincial Laboratory, which was first installed in 1884 at the hospital of St. Juan de Dios by Dr. Mendoza. It is here that bacteriology is taught. Deputed by the Spanish Government to study these questions in foreign countries, Dr. Mendoza received considerable assistance from Professor Koch at Berlin, and now the laboratory of the St. Juan de Dios Hospital has become a great centre for bacteriological analyses and investigations.

A Royal order of May 29th, 1897, approved the creation of the Brown-Séquard Institute, likewise under the direction of Dr. Mendoza. Here organic extracts are obtained and sterilised in the Aronsval apparatus with the aid of carbonic acid. The extracts are derived from the supra-renal body, cerebral, splenic, hepatic, testicular, ovarian, pancreatic, pulmonary, renal and thyroid glands, &c. Then there is the Micro-biological Institute, situated in the Argüelles, a thickly populated district of Madrid. The object of this institute is the manufacture of anti-diphtheritic serum and the study of all kindred questions. During the first three years of its existence this institute provided serum for the treatment of 730 cases of diphtheria. Deducting those who died within twenty-four hours of the commencement of the treatment the mortality was only equal to 9 per cent. In 1883 an institution for vaccinating with calf lymph was established by Dr. Balaguer in the Calle Preciados, which was subsequently supported by both the municipal and provincial authorities. In 1893, in consequence of an official order, this institute provided the means of revaccinating all the prisoners, both male and female, who were at that time in the Madrid gaols. The same had been done in regard to all the troops quartered in the town during the year 1890. Lymph was also forwarded from the institute to numerous towns and villages where epidemics of small-pox had broken out. In all, some 120,000 persons living in the provinces were thus vaccinated. But there is also what is known as the State Institute of Vaccination which was founded in 1872 for the culture of vaccine coming from the institutes of Dr. Lenoix at Paris and Dr. Negri at Naples. At first this institute only sought to vaccinate calves and to preserve the virus. Then some of the troops forming part of the garrison were brought here for vaccination and the few civilians who were sufficiently well informed to desire vaccination also came to the institute. In 1874 the institute was placed under the direction and inspection of the Academy of Medicine and in course of time it undertook the vaccination and revaccination of the general public. About 30,000 persons belonging to the civil population are vaccinated here in the course of a year. From this institute lymph preserved in Widal tubes and in capillary tubes is sent daily to all parts of Spain.

Needless to say, that in an ancient country like Spain, which was once a very wealthy country, there yet remain many old charitable foundations, such as hospitals, asylums, almshouses, &c. A volume might be written to describe all these institutions. For the moment it must suffice to allude only to those establishments which possess some peculiar feature or have a direct bearing on sanitary questions. Among the former the Provincial Hospital deserves special notice. It was founded in 1587, but a portion of the present structure was built under Charles III. This hospital contains 1000 beds and about 14,000 in-patients are received in the course of the year. The hospital is very old, badly situated, and not built according to modern principles of hygiene. The peculiarity about it is that in spite of these defects epidemics do not spread within the hospital. During the last outbreak of small-pox in Madrid many patients suffering from this disease were admitted yet no one in the hospital caught the complaint. In many other respects the evils which should result from bad sanitation fortunately fail to occur. It is true that the hospital is kept scrupulously clean, but this is scarcely sufficient to atone for the defects of construction. There is one explanation given for this immunity. The hospital was built in days of wealth and luxurious extravagance. Therefore to ensure solidity the walls were made no less than 6 ft. thick. As a consequence, it is said, the wards remain unaffected by the heat of summer or the cold of winter. It is not necessary to light fires. The heat of the summer, stored in the thickness of the walls, reaches the wards by the time the winter comes on and the walls have barely lost their heat when it is renewed by the returning spring. When sewage is thrown on the land the water, if gathered 2 yards below the surface, is found to be perfectly pure, and the walls of the Madrid Provincial Hospital are 6 ft. thick. Would 6 ft. of masonry have the same action as the soil of a well-organised sewage farm?

In contrast with this ancient hospital the Asylum of Santa Cristina may be mentioned. This institution has been recently created by his Excellency Señor Alberto Aguilera, who was Minister of the Interior when the International Congress of Hygiene met at Budapest and when it was invited to hold its next session at Madrid. Since that time Señor Aguilera has been Civil Governor of the Province of Madrid; and such are his popularity and influence that his presence in a crowd is always considered equal to at least 1000 soldiers. No one is better able to maintain order, and therefore all Governments prefer that he should remain Civil Governor of the capital rather than that he should have a seat in the Cabinet. But the influence Senor Aguilera has acquired is due, not merely to his ability and energy—it also arises from his unbounded benevolence and charity. By this time he might have been wealthy, yet it is notorious that he is poor, for he gives away all he possesses. Impressed by the number of beggars who infest the streets of Madrid, he determined to build an asylum for them where they might learn some useful handicraft. On the Moncloa slopes in the outskirts of Madrid he found a suitable site for this establishment. Such was his personal influence that he soon persuaded the owners to yield up the land; and, after giving all the money he possessed, succeeded in obtaining large donations from Her Majesty the Queen, the Marquis of Cuba and many others. A number of pavilions were then built which formed dormitories, with windows on each side and through ventilation. Already 200 beds are fitted up, and when the land is fully built over there will be 600 beds. In the centre of the grounds there is a chapel. Round the sides there are numerous workshops, where carpentering, blacksmith's work, tailoring, &c., are taught. Then the grounds are large enough to admit of lessons being given in market-gardening

Digitized by Google

and similar agricultural pursuits. Baths, washhouses, and a disinfecting stove ensure perfect cleanliness. The beggar from the street, and especially the children of beggars, may thus learn here how to become useful members of society and are also taught the gospel of cleanliness. All this has been done in an incredibly short time and such is Senor Aguilera's personal *prestige* that it is difficult to refuse him the help which he requires in carrying out this good work. This institution will materially contribute to raise the most deplorable sections of the Madrid population and will be as useful to the cause of sanitation as it is to that of public morals.

Close at hand, on the same hillside, is the Surgical Institute founded by Dr. Federico Rubio. This is a small model hospital where the only in-patients admitted are those on whom a serious surgical operation has to be performed. The wards are so arranged as to give the patients almost as much air as if they were out of doors. Complete antiseptic precautions are taken throughout and elaborate means of isolation are provided. The patients are allowed the greatest freedom and may receive their friends at any time. The nurses here are able to obtain technical training, while medical students may utilise the Rubio Institute as a surgical school. There are also large out-patient wards where some 600 consultations can be given in the course of a day. This is one of the most modern institutions of Madrid and is a model in its way.

To the north of Madrid there is a large fever hospital which consists of twenty separate pavilions. The whole is drained into hardware sewers with an abundant flush of water. The water used for drinking purposes is specially filtered in a Chamberland filter of 100 bougies. Thus there are two water-supplies, filtered and unfiltered. The grounds cover an area of 42,000 metres square in a good topographical situation and the soil is of impermeable clay. The pavilions are of iron, brick, and hardware, the soil is covered with asphalte, and the inside of the walls are painted in such a manner that they can be constantly washed. The most remarkable fact connected with this fever hospital is the smallness of the sum spent upon its construction. Though it is a permanent building it only cost £40 per bed, and there are in all 400 beds.

There are many other hospitals and asylums in Madrid, but for the most part these are ancient institutions and testify to what was done in the past rather than to the progress of the present day. The present purpose, on the contrary, is to signal out what bears trace of modern ideas and therefore the number of places described is necessarily limited. As, however, contributing actively to the growth of modern principles in sanitation the Spanish Society of Hygiene may, in conclusion, be mentioned. This society was founded in 1881. A solemn inauguration ceremony was held on April 23rd, 1882, at which His Majesty King Alfonso XII. presided. The society had previously been officially recognised by a Ministerial order as an institution of public utility. It is divided into five sections, as follows: epidemiology, climatology, demography, general hygiene and sanitary legislation. The professed purpose of the society is to study and diffuse a knowledge of all matters relating to hygiene and especially all that affects the healthiness of dwellings and food-supply. The meetings held by the members of the society are devoted to the discussion of such subjects and of all that may contribute to prolong human life. The society also exercises its influence so as to establish classes on hygiene in the universities and in the schools. Among the mass of the people it strives to spread knowledge by cheap pamphlets and popular lectures written or delivered in the simplest language. The society is particularly anxious to teach the poorest classes of the community how to render their homes more healthy. A considerable amount of time is devoted to seeking out the causes of the excessive infant mortality and to suggesting suitable remedies. The society also sends delegates to attend congresses held in foreign countries when questions of hygiene are discussed, and at home it attempts to influence the Government in favour of sanitary legislation. At the commencement of each year the Spanish Society of Hygiene holds a solemn opening sitting, at which a speech is delivered on some question of hygiene and the secretary reads a report on the work accomplished during the previous year. Then prizes are offered to the authors of the best and most practical tracts on hygiene. Some of these tracts have a wide circulation amounting sometimes to as many as 50,000 copies. In 1885 the society sent to the municipalities of Spain and various corporate bodies 10,000 copies of a manual giving instructions as to what measures should be taken to prevent the spread of cholera. A similar number of pamphlets have been given away dealing with the precautions to be taken against diphtheria and the best methods of disinfecting. Whenever an epidemic occurs, or when the death-rate is exceptionally high, the society immediately places itself in communication with the local authorities and offers technical advice and tracts on hygiene for distribution among the population affected.

Thus it will be seen that there are several institutions in Spain which seek to improve the sanitary conditions of the country. Undoubtedly there is much room for such improvement. The death-rate is still very high, but the fact that this death-rate can be reduced by sanitary measures is now realised, at least by the more educated sections of the population. Nor has the Government failed to encourage efforts in this direction. The authorities have, on the contrary, shown great readiness to patronise such institutions as seemed likely to be of service in improving public health. The great stumbling-block is the want of funds. Many towns in Spain, commencing with Madrid, require a new system of drainage. Such sewers as exist are badly built; they leak and contaminate the surrounding subsoil and are not self-cleansing. But to redrain a town is a very costly undertaking and the taxpayer is already overburdened. The first step, however—that of teaching the necessity of such measures—has been taken. The next will come in time, and then Spain will have good reason to be grateful to the pioneers who to-day are performing the arduous and often ungrateful task of spreading a higher knowledge of the principles and advantages of good sanitation.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Underground Lavatories.

THE construction of two underground lavatories in different parts of Birmingham will afford a convenience long required. The larger one near St. Martin's Church will be divided by separate entrances. One department will contain six water-closets, with an attendant's room and lavatory with two basins and dressing-tables. Hot and cold water will be provided, a geyser stove supplying the former. In the men's department seven water-closets and other conveniences are to be provided with two lavatories. The latest sanitary improvements will be made and a water-driven air propeller will provide the ventilation. In Corporation-street the second one is being built. Owing to the depth of the excavations and construction it is expected that the work will occupy until October next before completion.

British Medical Association.

The annual meeting of the Birmingham and Midland Counties Branch of the British Medical Association was held at the Medical Institute on June 16th under the presidency of Mr. Vincent Jackson of Wolverhampton. The presidential address was devoted to a history of the medical profession and the progress made in recent years. Some aspects of the daily life of medical men were touched upon and a lesson was drawn from the want of unity among professional men. The members subsequently dined at the Grand Hotel.

Midland Counties Home for Incurables.

The foundation-stone of a new wing for this home was laid by the Lord Mayor of Birmingham (Mr. Councillor Beale) on June 8th. The home was started in 1894 as a private institution and has since grown into proportions necessitating considerable additions. In the present plan provision is made for 33 additional patients, a new kitchen, and accommodation for servants. The cost is estimated at £17,000. It was stated that the home, which is situated at Leamington, received one-third of the subscriptions from that town while four-fifths of the benefit were obtained by the districts around. Of necessity this must be so when the area of population is considered. No doubt the appeal made to the larger town of Birmingham for help will meet with some suitable response.

Cycling Accidents.

The danger of the public streets is immensely increased by the great number of cyclists constantly passing through

Digitized by Google

them. Magisterial decisions as to responsibility do not seem to agree as to the liability of the cyclist to ring his bell to warn the pedestrian of his approach; in many instances the sound of the bell and the impact of the cyclist is simultaneous. Certain it is that many nervous people hesitate and place themselves in jeopardy by the warning given and opinions differ as to the desirability of sounding the bell as a note of warning. Still it is more frequently upheld that the fact of doing so is sufficient to relieve the cyclist of any responsibility attaching to an accident. It must be remembered also that the danger to the cyclist is often as great as it is to the pedestrian and that necessarily he would avoid incurring risk to himself. In a recent accident a woman was knocked down by a cyclist who was not going at a rapid pace. Her head struck against the kerbstone, causing fracture of the skull. She was conveyed to the hospital and trephined, but death resulted. A verdict of "Accidental death" was returned. Minor accidents connected with cycling have become very numerous and difficult to prevent.

The Holder Bed Fund.

A proposal to dedicate a bed in the new General Hospital to Sir John Holder by subscriptions limited to 1s. has met with a response so far of £500. As £1250 are required it is doubtful if the amount will be raised, worthy as the commemoration of such services is.

Death of Thomas Lant Smith, M.R.C.S.Eng., L.R.C.P.Edin.

At the advanced age of ninety-one years Mr. Smith passed away on June 29th at his home in the village of Alcester, Warwickshire. A type of a high-minded and honourable man Mr. Smith enjoyed the confidence of many friends. Ever ready to give his services to all who required them he lived among his people with mutual feelings of affection and regard. A trusted friend, a wise counsellor, and a beloved doctor, his memory will long remain dear to those among whom he lived and worked for so long a course of years. Mr. Smith was formerly house surgeon to the Westminster Hospital. He took the M.R.C.S. Eng. in 1829 and the L.R.C.P. Edin. in 1860. Of retiring disposition, he never took much part in public affairs, but his intelligence and powers of observation made him ever a charming companion and a reliable practitioner.

July 4th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Owens College.

THE opening of the Christie Library and the laying of the foundation stone of the Whitworth Hall, which took place on June 22nd, are events of importance in the history of Owens College. For the library, as the Duke of Devonshire, who performed the two ceremonies, told his audience, "the College is indebted to Mr. Christie as a purely personal gift," and to the Whitworth Hall Mr. Christie has devoted his share as a legatee under the will of Sir Joseph Whitworth, amounting to at least £50,000. It is a gratifying fact that in an age much given to extravagant ostentation and display instances like the above occur from time to time to show men a better and nobler way of using the gift of wealth. The library will be, it is said, though of the greatest value to every branch of education, of more special service to the students on the arts side than even to those on the science side of the college. It is no doubt well, as the Duke of Devonshire said, that Owens College has been "distinguished amongst the modern university colleges by the resolution with which it has persevered not to permit the arts side of its course altogether to be overshadowed by the scientific." In a manufacturing district like that in which the college stands, there is a great tendency to consider scientific knowledge merely as something convertible into "dollars," and it is well to be reminded occasionally that there is something loftier even than applied science.

The Recent Case of Poisoning at Crumpsall.

An inquiry was held on June 24th by the Manchester city coroner into the circumstances connected with the death of a woman at the Workhouse Hospital, Crumpsall. The cause of death was given by Dr. Reynolds, who made a post-mortem examination, as cerebral hæmorrhage consequent on consumption. She had been for some time in the imbecile ward and was sent over to the infirmary for active treatment. A dose of "Battley's opium sedative" was given by the nurse in mistake for another medicine of which ½ oz. was ordered, so that the patient had probably taken ½ oz. of "Battley." The nurse discovered her mistake at once and went for the house surgeon, who applied the stomach-pump. The patient shortly became insensible and died next morning. It seemed from the report of the evidence given by the superintendent of the nurses that this "Battley" is kept "in a small cupboard and stores" next to the poison cupboard as a matter of convenience, because "that medicine is given to the patients constantly." This suggests the question, Is this "Battley" given at the discretion of the nurse as it is kept "so handy"? Dr. Reynolds, the consulting physician to the workhouse, stated that the "deceased was not only insane but a mass of disease," and that it was impossible to say whether death was hastened by the Battley's mixture. The verdict was "in accordance with the medical evidence" and the jury "wished strongly to censure" the conduct of the nurse and head nurse. Though the facts given show that there was culpable carelessness in this case, it is only fair to say that the coroner stated that it was about twelve years since there was a similar case at the workhouse hospital. There are about 1000 persons in the infirmary and 2000 or 3000 doses of medicine are given in the day, so that, as he said, it is about one mistake to millions of doses. With a little more care there would be no mistake.

The Burnley Hospital Scandal.

The inquiry into this case, an account of which was given in THE LANCET of June 11th, has resulted in a report which must be consolatory to the board of guardians and to the hospital authorities. Each of these bodies has found that it was not to blame, so that they may be said to have been the victims of circumstances—just like the poor fellow who died.

Sanitary Inspectors' Association.

The North-Western and Midland Sanitary Inspectors' Association has been holding conferences in Manchester, and on Saturday last, July 2nd, they were addressed by Mr. Vacher, the medical officer of health of the county of Cheshire. He spoke of the report of the sanitary committee of the corporation as "a record of work prodigious in its extent," and of the position of Manchester as in the van of the army of sanitary progress. It is well to have the comments of an intelligent observer who can take a wider view than those who are so near the work as to see only the details close at hand. There are sins of omission and commission which are seen at once, and the enormous amount of good work quietly done is apt to be left unnoticed.

Manchester Volunteer Medical Staff Corps.

The two companies of the Volunteer Medical Staff Corps in Manchester were inspected on July 2nd, at Trafford-park by Surgeon-Colonel Scott, C.M.G., principal medical officer of the North-Western district. They mustered 218 strong and were under the command of Surgeon-Captain Coates. Surgeon-Colonel Scott spoke "in high terms of the efficiency of the corps, as proved upon that occasion and also during the recent encampment at Lytham."

July 5th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Meeting of the British Medical Association: Excursion to St. Andrews.

THE excursion to the ancient cathedral and university city of St. Andrews promises to be one of the most popular and enjoyable of the many offered by the association on the occasion of its visit to Edinburgh. The University and the Cathedral have in some senses been revivified and rejuvenated of late years. At the University new medical buildings are in process of erection, the gift of the Lord Rector, the Marquis of Bute, who takes a keen interest in the development of medical teaching at St. Andrews. The University has to thank the same generous donor for very liberal contributions to the Students' Union and also for several very fine oil-paintings of distinguished personages. The library of the University is one of the largest and finest

Digitized by Google

in Scotland and contains many rare books and manuscripts. The University museum—a model one in its way—is particularly rich in zoological specimens, minerals, and fossils, the collection of Dura Den old red sandstone fishes being unique. The new Marine Laboratory is deserving of special attention. It is beautifully situated on the margin of the sea, where an abundance of pure salt water and all kinds of zoological specimens can be obtained. It is equipped with every modern appliance and is the successor of a relatively very old marine laboratory which in its day attracted as original workers the foremost of British and Continental *savants*. Under existing arrangements the following science and medical subjects are taught at St. Andrews University: (1) mathematics, (2) physics, (3) botany, (4) zoology, (5) chemistry, (6) anatomy, (7) physiology, and (8) materia medica and therapeutics. The two *anni medici* or residential years required for medical graduation in the Scottish universities can now be taken at St. Andrews University. The St. Andrews golf links are the most celebrated in the world. Those members of the profession who are interested in golfing will have an opportunity of witnessing a masterly exposition of the game, as an exhibition match has been arranged between professional players for the gratification of the visitors. The St. Andrews climate is one of the driest and most bracing in the kingdom. The summers are refreshingly cool and the winters are crisp, bright, and open, with little frost and next to no snow. Nine months of nearly perfect weather out of the twelve can always be reckoned on. The three bad months (if bad they can be called) are March, April, and May, when east winds prevail. Fogs are unknown. Occasionally, but very occasionally, a sea fret makes its appearance. As a consequence the death-rate at St. Andrews is exceedingly low. The climatic advantages referred to are now being recognised by the profession and by parents having children to educate, with the result that patients and young people keep flocking into the city, which is increasing by leaps and bounds. Within the last ten years it has increased by nearly a third. The harbour, too, is being greatly enlarged and a sea esplanade formed. These point to a yachting station in the near future. The Madras College and board schools have something like 1000 pupils, while St. Leonard's and St. Katharine's Schools have over 250 boarders, to say nothing of day scholars. St. Salvator's, Clifton Bank, and Edge Cliffe Boys' Schools may be described as being in a chronic state of congestion. The Medical Faculty of the University naturally take the greatest interest in the proposed excursion and are, in conjunction with the local medical men, exerting themselves to make it a success. The Faculty with their Dean, Professor Bell Pettigrew, are issuing 200 invitations to members of the association to join them at luncheon in the town-hall, kindly placed at their disposal by the Provost of the city who has expressed his intention to be present on the occasion. As the local members of the profession have considerately arranged to provide afternoon tea in the beautiful grounds of St. Leonard's School, by the kind permission of Miss Grant, very little is being left to chance. A right hearty welcome awaits those who elect to spend the last day of the association meeting in "the grey old city by the sea," as St. Andrews was finely described by the late Dean Stanley, a former Lord Rector of the University.

St. Andrew's Ambulance Association.

The annual meeting of this association was held in Glasgow on June 28th, the Most Honourable the Marquis of Breadalbane, K.G., being in the chair. The annual report indicated the large area of usefulness occupied by the activities of the association and the increasing demands for ambulance service. The most important business submitted to the meeting was the draft of a proposed Crown charter of incorporation and authority was given to certain petitioners to forward this for the approval of Her Majesty's Privy Council. It is contemplated that this step will improve the status of the association, but if the prayer of the petition is granted certain practical advantages will also follow. The association if incorporated becomes a distinct *persona* in law with perpetual succession and the power to take donations, to hold lands and to invest money. The proposal to petition for a Royal Charter has the support of the medical members of the association and the convener of the committee in connexion with the proposal is Dr. George T. Beatson.

Faculty of Physicians and Surgeons, Glasgow.

Mr. Hugh Galt, M.B. Glasg., lecturer on Forensic Medicine in St. Mungo's College, having passed the necessary examinations, has been admitted a Fellow of the Faculty of Physicians and Surgeons, Glasgow.

The Reported Increase of Insanity.

Mr. J. Carswell, medical officer of the Barony Parish, Glasgow, deals with the above question in his annual report and on the basis of figures submitted concludes that "there are solid grounds for the opinion that insanity is not increasing in prevalence even in the face of figures that at first sight seem to prove the contrary."

Dundee Infirmary.

At the weekly meeting of the directors on June 30th the chairman announced that a cheque for £5000 had been received from Mr. John Sharp of Balmuir. The donation is from Mr. Sharp and his brothers and sisters in memory of their late father and mother.—Satisfactory arrangements have now been made between the directors of the infirmary and the authorities of University College, so that when the new professors have been appointed by the University Court of St. Andrews there will be in Dundee a completely equipped medical school which will be a college of St. Andrews University. The professorships of Therapeutics and Pathology are advertised and the appointments will be made in the course of the summer.

July 5th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Mercer's Hospital, Dublin.

AT a meeting of the Corporation of Dublin held on July 4th a letter was read from the governors of Mercer's Hospital asking for a continuance of the annual grant towards the funds of the hospital in view of counsel's advice that they cannot legally comply with the condition which the corporation has laid down as a *sine quâ non* to the continuance of the grant—viz., the election for one year of three members to represent the Corporation of Dublin on the board. During the discussion it transpired that the members of the hospital board could only be legally elected for life. A suggestion was made that some understanding could be come to by which the elected governors should resign at the end of one year. The corporation in the meantime refused to make the grant.

The Irish Medical Association.

The committee and council of the Irish Medical Association met at the Royal College of Surgeons, Dublin, on June 28th. The opinion of counsel was received relative to clause 86 of the Local Government Bill and its effect on "existing officers." A suggested amendment of the clause was also considered and agreed to, to be moved in the House of Commons on the report stage of the Bill.

An Ambulance Corps for Dublin.

The long-talked-of ambulance corps in connexion with the fire brigade of Dublin is at last about to be established. A site has been purchased in Buckingham-street in the proximity of the Quays and the city architect has submitted plans for the construction of the station, which will be built with as little delay as possible. In the meanwhile the brigade are to receive a regular course of instruction on First-aid to the wounded.

The Coombe Lying-in Hospital, Dublin.

The annual meeting of the directors and supporters of the Coombe Lying-in Hospital, Dublin, was held on June 30th, the Lord Mayor occupying the chair. The report, which was read by the master of the hospital, Dr. Frederick Kidd, showed that the institution was in a most satisfactory condition and continuing to do good work. In order to provide the nurses with more modern and better accommodation a collection is being made to which the Countess of Meath has recently contributed £50.

The Royal Victoria Hospital, Belfast.

The Belfast Corporation (Hospitals) Bill received the Royal assent on July 1st, so now that all opposition has been overcome the arrangements in reference to the new Victoria Hospital will, it is hoped, proceed rapidly. A good deal of trouble has arisen in reference to the provisions of the charter, especially in reference to the question of life

Digitized by Google

governors, but this has finally been settled, the compromise being that all the old life governors will retain their privileges, but that no new ones will be appointed in the same way. The charter will be submitted for approval to a committee of the subscribers to be held next week.

The Health of Belfast.

For the period between May 22nd and June 18th 499 cases of zymotic diseases have been notified—viz., 327 cases of typhoid fever, 83 of simple continued fever, 48 of scarlet fever, 20 of diphtheria, 16 of erysipelas, 2 each of puerperal fever and croup, and 1 case of typhus fever. There were 81 deaths from zymotic disease, 101 from phthisis, and 93 from diseases of the respiratory organs. The annual death-rate from all causes was 22·9, while for the same period in 1897 the deaths rate was 23·5. Cases of typhoid fever are becoming less numerous and those of scarlet fever and measles comparatively few and attended with little mortality. It is curious to note that although at this season the deaths from chest affections are becoming less numerous the high air temperature seems to have no effect in reducing the mortality from phthisis. Mr. Conway Scott, C.E., the executive sanitary officer of the Belfast Corporation, has, owing to ill-health, been obliged to obtain a month's leave of absence. It has been decided to appoint a practical civil engineer with a thorough knowledge of sanitary work as assistant executive sanitary officer at a salary of £200 with gradual increase to £250.

The Public Health Department of Belfast.

The Public Health Committee of the Belfast Corporation have for some time been considering the working of the department and have drafted a number of recommendations for its better arrangement, but owing to the absence of the chief sanitary officer (due to illness) their consideration has been postponed until his return.

The Belfast Water-supply.

The Public Health Department having drawn the attention of the Water Commissioners to the risk of contamination of one of their supplies at Stoneyford owing to pollution by sewage of one of the streams flowing into their works the Commissioners reply through their secretary that owing to storage and filtration the water is suitable and safe for domestic purposes. However, they are anxious to remove all ground for uneasiness in the public mind and this can only be done by purchasing a number of farms the proximity of which to the reservoirs might be regarded as detrimental to the water. This will probably require a Parliamentary Bill to be passed authorising the Water Commissioners to buy the land owned by these farmers.

Death of Mr. Martin Howard, L.A.H., L.M. Dub., of Oldham.

It was with sincere regret that many members of the Cork profession heard of the death of Mr. Martin Howard who for many years had been practising at Oldham. Mr. Howard was educated at the Queen's College, Cork, and whilst quite a junior in the profession was a constant contributor to the medical journals. He at all times had a great taste for literature and many years ago was officially connected with the London *Daily News* and the Dublin *Freeman's Journal*. He afterwards became assistant to a practitioner in Oldham and later, with the consent of his principal, who had formed a high opinion of him, started an independent practice in that town. His old love of journalism asserted itself and he became editor of the *Oldham Standard*. So great was his energy that he was able to perform his editorial duties and at the same time devote himself to the laborious work of a general practitioner. However, the strain proved too much for a constitution which was never robust. Last Easter he suffered from an attack of influenza and he never completely rallied. His death last week came as a painful surprise to his many friends in Cork who had been unaware of his failing health.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Prophylaxis of Tuberculosis.

AFTER a long discussion on this subject the Academy of Medicine, at their meeting on June 28th, unanimously agreed that the conclusions formulated by Dr. Grancher in his report to the Academy, which were given in THE LANCET of May 14th, 1898, should be adopted. These conclusions were shortly as follows: (1) all sputa should be collected in some vessel or receptacle containing at least 5 per cent. of carbolic acid; (2) sweeping should be as far as possible replaced by rubbing over with a damp cloth; (3) all milk to be boiled; (4) these measures to be strictly enforced by private practitioners attending on families where and as soon as tuberculosis is diagnosed; (5) early cases of tuberculosis occurring in the army to be invalided provisionally until the bacillus of Koch is demonstrated and permanently as soon as it is demonstrated; (6) the importance of hygienic and preventive measures to be urged upon those in charge of schools, workshops and the like; (7) isolation and antisepsis to be carefully carried out in hospitals where tuberculous patients are received; (8) the health of the permanent hospital staff to be more carefully looked after; (9) sundry regulations for the seizure of tuberculous meat and the use of tuberculin recommended to farmers and graziers as a means of diagnosis; and (10) the hygiene of the army to be more carefully attended to by means of improved rations, better ventilation of barracks, and the like.

The Value of the Anti-streptococcic Serum obtained from a Culture of Erysipelas Streptococcus.

At the meeting of the Biological Society held on June 25th M. Courmont gave an account of some experiments he had made with anti-streptococcic serum. He immunised an ass by inoculating it with a culture of streptococci derived from a case of human erysipelas and thus obtained a serum which rendered a rabbit perfectly immune against these streptococci. He had also isolated eleven kinds of streptococci from erysipelas or suppurating lesions in human beings and tried the serum obtained from the ass against these. Of the eleven different streptococci seven only were influenced by the serum. Even then, if an ass be inoculated with two samples of streptococci, it is not possible to obtain a serum efficacious against all kinds of streptococci, for the various kinds of this organism are too different for one anti-streptococcic serum to overcome them all.

The Curability of Fœtal Ichthyosis.

At the meeting of the Hospitals' Medical Society held on June 24th M. Thibierge showed two patients similiar to those individuals who are exhibited at fairs as "human fish." The two patients were aged respectively fifteen and eighteen years, thus showing that, contrary to the general opinion, fœtal ichthyosis is not necessarily fatal. They both presented in a diminished degree all the characters of fœtal ichthyosis. From birth they had suffered from ectropion owing to the thickening of the skin and very soon afterwards scales began to appear. These scales covered the whole body, including the articular surfaces, and in one patient they were regular horny plates which, however, almost entirely disappeared under treatment. In both the hands showed hyperkeratosis and hyperidrosis, which is not the case in ordinary ichthyosis. Both were of very low intellectual development; the father of the one was syphilitic and alcoholic, while the mother of the other suffered from psoriasis and had before given birth to a monster with only one lower extremity, but there was no other case of ichthyosis in the family.

Observations at the Execution of Carrara.

M. Capitan, who had occasion to be present at (*assister à*) the execution of Carrara, was able to note some physiological points which he communicated to the Biological Society at the meeting held on June 25th. On arriving at the guillotine Carrara was deadly pale and almost lifeless. He made not the slightest movement of resistance save only that his body seemed to shrink back when he was laid on the plank. Afterwards he never moved. When the knife fell the section of the neck on the body remained perfectly bloodless. As the body was being tilted into the basket it hit against the side of the plank and then two jets of red blood spouted in the air to the height of about a yard. In this case there was probably cardiac syncope present before the decapitation, whence the absence of hæmorrhage immediately after, although this came on in the ordinary way when the powerful nervous excitation provoked by the fall of the knife acted upon the heart.

The Toxicity of Normal and Pathological Sweat.

At the same meeting of the Biological Society M. Charrin and M. Mavrojanis reminded the society that in a previous

Digitized by Google

communication they had decided that the toxic dose of normal sweat was from 60 to 70 c.c. per kilogramme of body weight; they continued their researches by making extracts of sweat both with alcohol and ether and they found that its toxicity was due in the proportion of about two-thirds to substances soluble in ether, most probably fatty acids. They also discovered that there were certain substances insoluble both in ether and alcohol which were capable of setting up grave gastro-intestinal disturbances and a very marked and persistent fall in temperature. Sweat freed from substances soluble in ether causes death, but the dose ought to be triple that of the ordinary toxic dose. Sweat taken from patients suffering from acute infectious maladies was, in accordance with the researches of Queirolo and Salter, sensibly increased in toxicity. A subcutaneous injection made into a healthy guinea-pig of doses of sweat of from 25 to 30 c.c. per kilogramme of body weight produced during two or three days a rise in temperature of from 1·5° to 2°C. and sometimes brought about death in the space of 24 hours. Sweat sterilised in an autoclave at 110°C. for 20 minutes acted in the same way. The sweat collected immediately after a seizure in an epileptic patient and injected into the venous system of a rabbit brought on forcible extension of the vertebral column, but never marked convulsions or death. In the case of melancholiacs the toxicity of the sweat is not increased.

July 5th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of Asphyxia produced by Anæsthetics.

DR. HERZOG of Charkow has recently published in the *Deutsche Zeitschrift für Chirurgie* some experiments made according to Dr. Laborde's method of producing resuscitation in cases of chloroform and ether asphyxia by rhythmical traction of the tongue. The effect of making traction on the tongue is to stimulate its sensory nerves and to bring about reflex contraction of the respiratory muscles through the medium of the central nervous system. Dr. Laborde recommends that the tongue should be seized firmly and that traction should be made about twenty times in a minute. Up to the present time 12 cases have been recorded in which this method proved successful in asphyxia from anæsthetics. For the purpose of testing Dr. Laborde's conclusions Dr. Herzog made a series of experiments on dogs partially asphyxiated by means of large doses of chloroform and ether and found that in 19 cases respiration was restored spontaneously in 6, but that traction of the tongue was only successful in resuscitating 3 of the remaining 13. In these 3 instances the animals began to breathe again after traction had been made twelve times, and their recovery was complete; in 2 other cases respiration was restored, but the cardiac action nevertheless failed and although the respiration was kept up for sixteen and six minutes respectively the pulse did not rally and the animals died. The results obtained by Dr. Herzog are thus at variance with those of Dr. Laborde, who obtained resuscitation in the great majority of cases. It is probable that Dr. Laborde commenced to make traction of the tongue at an early stage when the animals were still capable of recovering spontaneously. The asphyxia obtained in Dr. Herzog's experiments always occurred in the last stage of the narcosis. Asphyxia in the early stage of the narcosis, while it is so frequent in the human subject, could not be obtained in the experiments on animals. Dr. Herzog concludes that Dr. Laborde's method is not reliable in the asphyxia of the last stage of narcosis, but that it may be tried as an auxiliary to other methods in the primary stages.

The Giving of Medical Advice by the Clergy.

The Roman Catholic Bishop of Augsburg has recently made a communication to the clergy of his diocese on the subject of the increasing tendency of the clergy to give advice in cases requiring medical treatment—a practice which he condemns as being at variance with the ordinances of the Church, and he charges his clergy to avoid anything which may have the appearance of interfering with the work of the medical profession. This order is the more remarkable because Woerishoffen, where the late Father Kneipp lived and where his successors still continue his work, is in this diocese. The expression of similar views by other clerical dignitaries would no doubt have a beneficial influence as tending to prevent misunderstandings between the two professions. That quackery has its most fervent adherents among the upper classes was clearly shown by a recent occurrence. One of the leading newspapers of Berlin published a letter written by a medical man showing that a so-called "magnetopath" had pretended to cure patients by means of magnetic fluid coming from a well-known Berlin medium now resident in America. This medium had formerly caused a certain amount of sensation in connexion with spiritualist meetings but eventually left the city when it was shown by some medical men that she had been carrying on a system of imposture, and it was by means of the fluid of this medium that the "magnetopath" professed to effect his cures. A few days after the insertion of this letter a public declaration appeared in the advertising columns of the leading Berlin journals, signed by a great number of patients of the quack. The signatures were for the most part those of members of the nobility and of the upper classes, who solemnly stated that they had been cured by this man after having been attended without success by legally qualified medical practitioners. The great popularity of every kind of quack treatment among the upper classes leaves little ground for hope that unqualified practice will be made illegal.

July 5th.

Obituary.

HENRY ALFORD, F.R.C.S. ENG. (HON.), L.S.A. LOND.

MR. HENRY ALFORD recently died at his residence, South-road, Taunton, from old age. The deceased received his medical education at the Bristol Medical School and St. Bartholomew's Hospital, London, qualifying as L.S.A. in 1828 and as M.R.C.S. Eng. in the following year. In 1844 he was admitted to the honorary Fellowship of the College. MR. ALFORD had resided in Taunton since 1830, being formerly surgeon to the Taunton and Somerset Hospital, and at the time of his death was consulting surgeon to that institution. The deceased was one of the most respected and oldest inhabitants of Taunton and had he lived until July 17th would have been ninety-two years of age. In spite of this great age he retained his health until a fortnight before his death. Mr. Alford will be greatly missed in Taunton, where he had assisted in many good works, especially taking a great interest in the hospital. The deceased was a cousin of the late Dean Alford of Canterbury and also of the late Bishop Alford of Victoria. Mr. Alford was twice married and leaves four children, one of whom is the present medical officer of health of Taunton.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ELECTION OF MEMBERS OF THE COUNCIL.

THE tenth election of Fellows to fill the vacancies in the Council of the College under the new regulations was held in the Library of the College, Lincoln's-inn-fields, on Thursday, the 7th inst., between 1.30 and 4 P.M. The result of the voting was as follows:—

	Votes.	Plumpers.
MR. RICHARDSON CROSS ...	411 ...	... 74
MR. HENRY MORRIS	325 ...	... 7
MR. JOHN LANGTON	322 ...	... 15
MR. R. CLEMENT LUCAS	274 ...	... 53
MR. BENNETT MAY	248 ...	... 26

Mr. Langton and Mr. Morris were therefore re-elected members and Mr. Cross was elected a member of the Council.

651 Fellows voted by proxy, 26 voted in person, and one voting paper was spoiled.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND OF SURGEONS.—The following gentlemen passed the Second Examination of the Board in the subjects indicated on Monday, July 4th, viz.:—

Anatomy and Physiology.—Hugh Nevill Keeling, Yorkshire College, Leeds; Cyril Henry Hawkins, Mason University College, Birmingham; Thomas Sidney Davies, Herbert James, John Cecil Clayton, Charles W. Wanklyn James, and Kenneth Harold Beverley, University College, Bristol; John Hilton Ashton, Owens College, Manchester, and Surgeon's Hall, Edinburgh; Charles A. Gayer Phipps and Ernest Guy Jones, Owens College, Manchester; John Elder MacIlwaine, John Campbell Rankin, and Howard Stevenson, Queen's College, Belfast; Laurence Unthank Geraty, Royal College of Surgeons, Dublin; Louis Cornelius Driscoll, Charing-cross Hospital; Lachlan Gollan, Melbourne University and St. Mungo's College, Glasgow; William Pettigrew, Firth College, Sheffield; and Guillermo Gómez, University of Bogota and University of Columbia.

Anatomy.—William Beck, Aberdeen and Edinburgh Universities.

Physiology.—James Wodderspoon Bennett, Owens College, Manchester and Mr. Cooke's School of Anatomy and Physiology; Alfred Newman Leathem, Charing Cross Hospital; and Charles C. Tandy Magee, Melbourne University and London Hospital.

Fourteen gentlemen were referred in both subjects, three in anatomy, and one in physiology.

Tuesday, July 5th:—

Anatomy and Physiology.—Lawrence Pick, Herbert Pye-Smith Devitt, and James Farquharsen Powell, St. George's Hospital; Hugh Milville Raven and James Warner Elliott, St. Mary's Hospital; James Sydney Pascoe, Charing-cross Hospital; Lionel Gordon Hopkins, Julian Craig Fleming, William Reith John Scroggie, and Edward Salterne Litteljohn, University College, London; Vernon Montague Wallis and George Jepson Lewis, Guy's Hospital; Leo Hirsch, Grant Medical College, Bombay, and Guy's Hospital; John Crosthwaite Bridge and Percy George Pavitt, Middlesex Hospital; Robert Small, St. Thomas's Hospital; Percy Stanley Hopkins, Edinburgh University, St. Thomas's Hospital, and Mr. Cooke's School of Anatomy and Physiology; Charles Harold Turner, Reginald Thompson, and Hans Hill Sloane, St. Bartholomew's Hospital; Ireton George Pritchard, King's College, London; and Israel Stusser, London Hospital

14 gentlemen were referred in both subjects.

UNIVERSITY OF OXFORD.—At the examinations for the degree of M.B., B.Ch. the following candidates were successful in the subjects indicated:—

FIRST EXAMINATION.

I. Organic Chemistry.—C. H. Barber, non-Collegiate; G. E. Barry, Trinity; C. L. Goode, Hertford; A. G. Gibson and A. H. Hogarth Christ Church; P. A. Mansfield, Keble; J. E. Rutherford, Corpus; and R. H. Sankey, Christ Church.

II. Materia Medica.—G. B. D. Adams, Christ Church; G. D. Allen and C. H. Barber, non-Collegiate; A. W. Brodribb and J. Freeman, University; A. G. Gibson, Christ Church; F. L. Golla, Magdalen; A. C. Goodwing, Keble; T. Harris, non-Collegiage; A. H. Hogarth, Christ Church; C. M. H. Howell, Trinity; F. Howson, non-Collegiate; H. L. Laws, Wadham: H. C. Lecky and T. G. Longstaff, Christ Church; P. A. Mansfield, Keble; L. D. Neave, Merton; L. J. J. Orpen, Keble; D. R. Pike, Jesus; C. Rolleston, New College; P. F. Tinne, Magdalen; E. H. White, University; A. R. Wilson, Wadham; and H. M.M. Woodward, Keble.

III. Anatomy and Physiology.—L. H. Badcock, Trinity; E. C. Bevers, St. John's; G. C. Davidson, New College; O. Hildesheim, Magdalen; E. H. Hunt, Balliol; A. J. Jex-Blake, Magdalen; L. J. Picton, Merton; W. B. Prowse, Pembroke; O. W. Richards, New College; W. V. Shaw, Christ Church; G. F. D. Smith, New College; M. F. Tylor, Trinity; and C. E. A. Wilson, Christ Church.

FINAL EXAMINATION.

E. F. Buzzard, Magdalen; J. Fortescue-Brickdale, Christ Church; E. R. Frazer, Balliol; M. H. Gordon and C. N. Groves, Keble; L. H. Lindley, Magdalen; A. W. Oxford, Christ Church; R. C. B. Wall, Queen's; W. A. P. Waters, B.N.C.; and R. Whittington, Merton.

UNIVERSITY OF GLASGOW.—The following have passed the fourth (final) professional examination:—

A. For degrees of M.B., C.M.—John Donald, William Kilpatrick Hutton, M.A., James Millar, James William Otto van Millingen, William Fullerton M'Ewen, Samuel M'Lean, Charles David Picken, Thomas Boyd Riddall, and Charles Edward Cortis Sanford, B.Sc.

B. For degrees of M.B., Ch.B.—John Aitken, George Alexander, Arthur James Ballantyne, Robert Fisher Ballantyne, Andrew Aitken Barclay, James Barrowman, William Bennett, John George Wilson Boleyn, Theodore Belchambers Broadway, John Brunton, John James Buchan, Ranald Douglas Campbell, James Carruthers, M.A., Robert Carswell, M.A., John Crow, John Ronald Currie, B.A. Oxon., Robert Douglas, M.A., Kenneth M'Kenzie Duncan, Robert Fullarton, M.A., Alexander Garrow, David Sloan Harvey, Edward William Reese Jones, John Wilson Leitch, M.A., Alexander Millar Lindsay, Alexander Matheson, James Blakely Miller, James Alexander Mitchell, Percival Ambler Mitchell, Murdoch Macdonald, Archibald Turner Macewan, Laurence Abel Mackenzie, Dugald M'Kinlay, Alfred Duncan Macnair, Roderick Reid Macnicol, M.A., William Gardner Neill, Robert Niven, Percival Leslie Pearce, Joseph Wilkie Scott, John Macfarlane Sloan, William Hart Steel, B.A., Francis Stevenson, Frederick Ernest Stokes, Peter Donald Strachan, M.A., Thomas Morton Strang, Andrew Taylor, Robert Andrew Hannan Watson, William Webster, James Patterson Wilson. Women. — Daisy Annabelle Bennett, Agnes Forbes Blackadder, Mary Gardner, Jane Grant, Mary Longmire, Eva M'Call, Mabel Catharine Poulter, Jean Effie Prowse, Marion Jamieson Ross.

THE ROYAL COLLEGE OF PHYSICIANS OF IRELAND.—The following candidates, having passed a special examination for the Licence in Midwifery of the Royal College of Physicians of Ireland, were admitted Licentiates on Friday, July 1st:—

Arthur Cooper Fenn, L.S.A., and Kyran Hutchinson White, L.R.C.P. & S. Edin., L.F.P. S. Glasg.

ROYAL COLLEGE OF SURGEONS IN IRELAND: SUMMER PRIZE LIST.—Barker Anatomical Prize: Miss K. F. Lynn, first, £26 5*s.*, and J. S. P. Stewart, second, £15 15*s.* Carmichael Scholarship: C. R. Boyce, £15. Mayne Scholarship: D. Hadden, £15. Gold Medal in Operative Surgery: G. W. Little. Silver Medal in Operative Surgery: T. G. N. Stokes. Certificate of Merit in Operative Surgery: S. R. Godkin. Practical Histology: J. P. Byrne, £3 and medal, and R. H. Oulton, £1 and certificate. Practical Chemistry: W. Delaney and Miss M. J. Shire (equal), £2 and medals. Public Health and Forensic Medicine: D. A. Fitzgerald, £3 and medal, and Mrs. H. L. Hennessy, £1 and certificate. Materia Medica: J. Levis, £3 and medal, and W. R. Meredith, £1 and certificate. Practical Pharmacy: E. Evatt, £3 and medal, and Miss M. J. Shire, £1 and certificate. Biology: Miss M. J. Shire, £3 and medal, and R. E. Humphrey, £1 and certificate. The preliminary examination for the commencement of medical study will be held on Tuesday and Wednesday, Sept. 27th and 28th.

THE dinner of the Seventh Decennial Contemporary Club of St. Bartholomew's Hospital, which was held on July 6th at Frascati's Restaurant, was made the occasion of presenting Mr. A. A. Bowlby with a service of plate as a wedding gift from members of the club. Dr. John Mason, who was in the chair, as one of Mr. Bowlby's oldest friends, in proposing his health referred to the many services rendered to the club and above all to students of the hospital by him whom they had assembled there that night to honour. There was hardly anybody in the room, to say nothing of other members of the hospital who were by the constitution of the club prevented from being there that night, whom Mr. Bowlby had not assisted by kindly advice or suggestion. He would ask Mr. Bowlby in the name of the club to accept the service of plate before him with their heartiest wishes for the happiness of himself and his wife. Mr. Bowlby, as soon as the cheers allowed him to speak, briefly tendered his warmest thanks.

DIPHTHERIA IN LONDON.—The registered deaths from diphtheria in London have continued to be few in number as compared with earlier periods for many weeks now, and the week ended June 18th proved to be no exception. It is true that the number of such deaths in that week was a trifle above the total of the week preceding it, but that does not affect the statement. In the three weeks ended June 11th the deaths had been 27, 30, and 23 respectively, and though they rose in the succeeding week to 26 this latter total was itself 12 below the corrected decennial average for the corresponding week of the ten years 1888–97. There were 3 deaths each in Hackney and Bethnal Green sanitary areas. None of the deaths were of infants, but 16 were of children under five years of age and only one occurred of a person aged over twenty years. In the Outer Ring 10 deaths were registered from the disease, of which 3 took place in West Ham, 2 in Dartford, 2 in Hendon, and 2 in Edmonton registration areas. In the four weekly period ended on June 18th the deaths from diphtheria registered in London were, as may be expected, fewer in total than in the case of the like previous period ended on May 21st. The 117 deaths of the May period, with a weekly average of 29, gave place to 106 in the June period, yielding a weekly average of 26. Nevertheless the notifications of the earlier period were exceeded in June, the respective totals being 763 and 828, and the weekly averages 191 and 207. In the May period all sanitary areas of London save one were invaded, only one had more than 50 notified cases, whilst other three had only 3 cases in all. In the June period two sanitary districts escaped invasion again, only one area had more than 50 notified cases and other five invaded districts had but 14 cases notified among them. In the matter of case mortality naturally the June period showed the most satisfactory data—namely, 12·8 per cent., as against

Digitized by Google

15·3 per cent. in the May period. In the Outer Ring the total of deaths registered from diphtheria was precisely that of the preceding four weeks, 45. As regards the weeks after June 18th, during that ended on June 25th the registered deaths from diphtheria in London fell in number to 21 and were 15 below the corrected decennial average. Chelsea and Camberwell sanitary areas were each of them credited with 4 deaths and 3 occurred in Lambeth. Three of the deaths were of infants and the other 15 took place in the period one to five years, no person aged over twenty years being among the fatal cases. In the Outer Ring there were 11 deaths registered from the disease, including 5 in the Edmonton registration district. Last week the deaths registered in London rose again to 28, but were still 9 below the corrected decennial average. In the Outer Ring the registered diphtheria deaths again numbered 11.

CAMBRIDGE GRADUATES' MEDICAL CLUB.—The annual dinner of this club was held at Limmer's Hotel on June 30th, the President, Dr. W. H. Dickinson, being in the chair. Including members and guests 59 persons were present. After the usual loyal toasts the Chairman proposed that of the club. He referred to the great loss sustained by the club in the death of Professor Roy and alluded to his work in experimental pathology. He also touched on the present financial position of the Cambridge Medical School and the approaching Physiological Congress to be held at Cambridge. The toast was coupled with the name of Dr. Rolleston, who is retiring from the post of senior secretary after admirably filling that office for eight years. Professor Kanthack proposed "The Guests," coupled with the name of Professor Burdon Sanderson who duly replied. After Dr. Hare had proposed the Chairman's health the proceedings terminated.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—An ordinary meeting of this society was held at 20, Hanover-square on June 29th, the President, Dr. Radcliffe Crocker, being in the chair.—Dr. Rufenacht Walters read a short paper descriptive of a Papular and Urticarial Rash in a Dog. It was apparently due to "red mange." The dog was exhibited. The rash had been communicated to Dr. Walters's children and to another child.—The President showed a case of Large-spored Ringworm in a girl, aged eight years, and a case of Multiple Lupus Verrucosus in a girl, aged thirteen years, which had existed for twelve years, starting after an attack of varicella.—Mr. Pernet showed for Dr. Savill an example of (?) Angio-neurotic Affection in a woman; the case had been previously brought before the society during the past session.—Dr. A. Eddowes showed a Girl suffering from Morphœa.—Dr. Walsh showed a girl, aged eighteen years, with a congenital Elephantiasis of the Right Eyelid combined with a Lymphangiomatous condition of both the Ocular and Palpebral Conjunctivæ.—The cases and paper were discussed by the President, Dr. A. Eddowes, Dr. Phillips-Conn, Dr. Walsh, Mr. Pernet, and others.

UNIVERSITY COLLEGE, LIVERPOOL.—The Lord Mayor of Liverpool formally opened the new museum and school of hygiene in connexion with University College, Liverpool, on July 4th, in the presence of an influential gathering. The title of Ashton Hall has been given to the building comprising the new museum and school of hygiene, whilst the work of the pathological and bacteriological department is also temporarily carried on there. In 1895, pending the erection of suitable pathological laboratories, the late Mr. George Holt purchased the block of buildings now known as Ashton Hall and converted them into temporary premises for use by the pathological department of the College, of which mention was made in THE LANCET. It had been Mr. George Holt's wish that the building should subsequently be devoted to some branch of medicine having for its object the promotion of public health. After the formal opening of Ashton Hall the visitors were conducted over the new museum, which contains excellent models illustrating house sanitation in every detail, the construction of roadways, and other engineering works. There is also a complete system of models, preparations, and drawings illustrating the water-supply of the city from the source of origin to its destination. Some interesting curios are also to be found in the museum, such as old Roman stone water-pipes, earthenware water-pipes, ancient Persian tiles, &c. The building is well equipped for the purpose of sanitation. The purification of water and sewage and the action of disinfectants can all be carried out experimentally. The course of lectures on Sanitation was commenced in October, 1897, various efficient lecturers having been obtained for the purpose. There can be no doubt that the new school of hygiene will have a most important influence on the future sanitation of the city.

DR. J. A. CAMPBELL, who has so ably filled the post of medical superintendent of Garland's Asylum for a period of twenty-five years, is about to retire from that office.

THE Foundation Stone of the Nurses' Home, in the Marylebone Road, in connexion with Queen Charlotte's Lying-in Hospital, was laid by Lady Portman on Wednesday, July 6th.

THE first meeting of the Executive Council of the East Suburban Medical Protection and Medico-Ethical Society will be held at West Ham Hospital, Stratford, at 4 P.M. on Thursday, July 14th. Members are particularly requested to give the honorary secretary, Mr. Murtaugh Houghton, at the hospital, as long notice as possible of any business which they wish placed on the agenda.

UNFOUNDED CHARGE AGAINST A MEDICAL OFFICER.—At the meeting of the Helston (Cornwall) Board of Guardians held on June 25th a male pauper made a complaint that one of the medical officers (Mr. B. C. Kendall) would not give a certificate of death in the case of a child whom he had not seen for nine weeks. A resolution was unanimously passed exonerating the medical officer from all blame and the complainant was informed by the chairman that it was he, and not the surgeon, who had neglected the child.

A NEW HOSPITAL FOR SOUTH LONDON.—The Bishop of Rochester presided on Tuesday evening last at a public meeting in the Horns Assembly Rooms to support a scheme for transferring the Belgrave Hospital for Children to a site in the Clapham-road adjoining St. Mark's Church, Kennington. His lordship mentioned that the scheme was being warmly supported by the Duke of Westminster, who had issued an appeal for £50,000, the amount required to carry the scheme into effect. The secretary stated that between £4000 and £5000 had been promised, the Duke of Westminster and Mr. Douglas Freshfield heading the list with £1000 each. A resolution pledging the meeting to support the scheme was unanimously adopted.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Poisons Bill.

THIS Bill has passed through all its stages in the House of Lords and has been sent down to the House of Commons. It now contains a provision designed to meet the views of persons interested in the sale of disinfectants.

The Vaccination Bill.

THE Vaccination Bill, after engaging the attention of the Grand Committee on Law during seven sittings, has been reported to the House of Commons as amended, and it now falls to be considered by the House in the report stage. As the House has a great deal of other work in hand it may be some time before it is taken, and there is just a risk that it may be crowded out altogether.

HOUSE OF COMMONS.

THURSDAY, JUNE 30TH.

Phosphorus Matches.

Mr. MONK asked the Home Secretary whether he was aware that safety matches of a better quality than those introduced from abroad and of which yellow phosphorus was not a component part, could be readily manufactured in this country and be retailed in London and the provinces at 1½*d.* per dozen boxes; and whether he would consider the desirability of obtaining power to make the sale of phosphorus matches illegal, as injurious to the health of the operatives and dangerous to those who use them.—Sir M. WHITE RIDLEY replied: Yes, I am aware that safety matches of British manufacture which claim to be made without yellow phosphorus can be bought at about the price named, though I can hardly, I think, though I have had the advantage of a present of a box from my hon. friend, enter upon the question of their comparative quality. As regards the second paragraph I must await the results of the inquiry now being made at home and abroad before coming to any decision; but the hon. member is no doubt aware that it is claimed that by the adoption of certain methods the use of white or yellow phosphorus can be rendered harmless.

Work in Bakehouses.

On the motion of Mr. WOODS a Bill was introduced and read a first time to restrict the hours of labour in bakehouses to 48 per week.

FRIDAY, JULY 1ST.

Eastbourne Convalescent Hospital.

Captain NORTON asked the Under Secretary of State for War whether he could state if the existing convalescent home for soldiers at Eastbourne with 16 beds was found to suffice for the requirements of the troops stationed in the United Kingdom, seeing that, according to the Army Medical Department's report for 1896, the average admissions to hospital number 64,395, with an invaliding list of 2173 and a constantly sick rate of 3844.—Mr. POWELL WILLIAMS, in reply, said that the convalescent hospital at Eastbourne contained 20 beds and was established originally for the troops in London. It was not sufficient for the whole of the troops in the United Kingdom, whose sick were not sent to convalescent homes, but treated in the various station hospitals.

Vaccination Defaulters.

Mr. STEADMAN asked the Home Secretary if his attention had been called to a statement made by a police-inspector when applying for distress warrants in cases of non-payment of fines by vaccination defaulters. In reply to a question from the magistrate (Mr. Lane) the inspector said he was acting under instructions from the Home Office. And whether, seeing that the Local Government Board now admitted that "adventitious" germs were in vaccine lymph, and that therefore there was a justification in parents refusing to run risks, he could see his way to extend the instructions for application for distress warrants. —Sir M. WHITE RIDLEY replied that his attention had not been drawn to the statement otherwise than by the question, but it was the practice of the Home Office to take steps after proper inquiry as to the circumstances to enforce outstanding fines in cases of different kinds, and the statement was perhaps made in some cases in which such steps had been taken. He did not see his way to give the instructions suggested in the second paragraph.

MONDAY, JULY 4TH.

Rabies.

Mr. WALTER LONG, in reply to Mr. CROMBIE, said that in the course of the operations of the Board of Agriculture against rabies it had been found necessary to apply muzzling orders to the whole or parts of 32 counties; the number had now been reduced to 19. There had been 12 cases of the disease during the first 26 weeks of the present year, as against 88 in the corresponding period of last year, 327 in 1896, and 413 in 1895.

Coroner and Medical Evidence.

Mr. TENNANT asked the Home Secretary whether his attention had been called to the death of Thomas Sargeant, aged fifteen years, from "gassing" by benzol, in the Whitwood chemical works at Normanton about a fortnight ago, and to the circumstances attending the inquest; whether there were no regulations controlling the manufacture or use of benzol; and, if so, whether the desirability of instituting some regulations would be considered; and whether, seeing that the coroner had upon previous occasions dismissed applications for inquiry into matters having the gravest results, any action could be taken on his refusal to institute a medical examination into so serious a misadventure.—Sir M. WHITE RIDLEY replied: Yes, sir, a report has been received from the inspector and the case is still under inquiry. Therefore I am hardly in a position at present to state what steps it may be necessary to take. I regret the action of the coroner. Without wishing to prejudice the matter, I may say that it appears to me that it is much to be regretted that no post-mortem examination was made and no medical evidence given before the jury. But I am looking into the matter.

TUESDAY, JULY 5TH.

Experiments on Living Animals.

Mr. BARRINGTON SIMEON asked the Home Secretary whether his attention had been drawn to the last report of the inspector under the Act relating to experiments on living animals; whether he had observed that seven licensees confessed to having committed offences against the law, of which two consisted in two persons going on vivisecting in 1897 without the requisite licence, and that the inspector, having treated these two persons in the same way as licensed persons, condoned their offences; would he state who these persons were and whether any remonstrance, reprimand, or other communication had been or would be addressed to them.—Sir M. WHITE RIDLEY replied: Yes, certainly, I am aware of the facts stated in the inspector's report to myself. The nature of the irregularities referred to is shown in the report, and it will be seen that in every case they arose from inadvertence. It is not the fact, however, that the irregularities were condoned; letters of reproof were sent and in some cases severer measures taken. No good object would, I think, be served by publishing the names.

The Herbert Hospital at Woolwich.

Mr. BRODRICK, in reply to Captain Norton, said that on June 24th 342 soldiers were in the Herbert Hospital at Woolwich.

THE VACCINATION BILL.

PROCEEDINGS IN THE GRAND COMMITTEE.

The Grand Committee of the House of Commons on Law met on Friday, July 1st, with Sir HENRY CAMPBELL BANNERMAN in the chair, and continued the consideration of the Vaccination Bill.

Clause 3 of the Bill as introduced was to this effect: "The Local Government Board shall have the same powers of making rules and regulations with respect to public vaccinators (whether under contracts made before or after the *passing of this Act*) as they have with respect to vaccination officers, and any rules or regulations made by the Board with respect to vaccination, whether under this or any other Act, shall, while in force, have effect as if enacted by this Act."

Mr. CHAPLIN moved to substitute for this a provision that the Local Government Board "may make rules and regulations with respect to the duties and remuneration of public vaccinators whether under contracts made before or after the passing of this Act."

Mr. BRIGG said that this amendment did not get rid of his objection to the clause and asked whether it was meant that the Local Government Board should be able to give orders to the public vaccinator to prosecute without the authority of the board of guardians.

Mr. CHANNING insisted that the effect of the amendment would be to resuscitate and reinforce Article 17 of the General Order of the Local Government Board which instructed the public vaccinator to institute prosecutions, and he condemned this as an interference with the rights of boards of guardians.

Mr. CHAPLIN explained that his amendment related solely to the remuneration and duties of the vaccination officers and in no way affected the regulations as to prosecutions, which would have the force of law until they were repealed. It was necessary that the Local Government Board should have the proposed power because the vaccination officers would have new duties to perform in making domiciliary visits.

The amendment was then agreed to by the Committee.

Mr. BRIGG moved to add at the end of the clause, "But such rules and regulations shall not come into operation unless they have been laid upon the table of the House for forty days and have been sanctioned by the House."

Mr. CHAPLIN, opposing this amendment, said it had long been the practice of Parliament to leave these matters of detail to the determination of the department concerned and he saw no reason for an exception in this instance.

After a short debate the amendment was by leave withdrawn.

Mr. CHANNING suggested that there should be added to the clause words making it clear that the rules and regulations were to refer only to the duties and remuneration of public vaccinators in connexion with the new policy of domiciliary visits.

Mr. CHAPLIN undertook to consider the suggestion before the report stage of the Bill.

Clause 4, "The enactments mentioned in the schedule to this Act are hereby repealed to the extent specified in the third column of that schedule," was agreed to without debate.

On Clause 5, which says, "This Act shall not extend to Scotland or Ireland. This Act shall come into operation on the first day of January, 1899,"

Mr. BRIGG moved to alter the date to Jan. 1st, 1901. He explained that his object was to allow members of boards of guardians who were opposed to vaccination to retire before the Act came into operation and so to avoid friction.

Mr. CHAPLIN said he could not accept this proposal. He believed in the merits of the Bill and of the improved form of vaccination which it would introduce and he was anxious to see the measure in operation at the earliest possible moment If there were any guardians who found their conscientious objections so deeply in conflict with the new law they could retire and so obviate any difficulty such as the hon. Member contemplated.

Mr. CHANNING, supporting the amendment, said he regarded the Bill as a prodigious act of folly on the part of the Government and he thought it was the duty of this Committee to do something to protest against bad legislation and a measure which would bring about intolerable relations between the central government and the local authorities.

Mr. BAYLEY also spoke in support of the amendment.

Mr. LOGAN thought there should be this delay to enable scientists to complete their inquiries into the value of glycerinated calf-lymph. This form of calf lymph, he said, had not got beyond the experimental stage and it was monstrously unfair to the poor people of the country to force it upon them

Sir WALTER FOSTER spoke of the amendment as a very extraordinary one and said that however bad the Bill might be in some respects it conferred on the public many advantages, and he did not see why these advantages should be delayed.

The amendment was rejected by 21 to 6 votes.

Mr. CHAPLIN moved to insert in the Bill the following new clause—viz., "The Local Government Board may by order, if in their opinion it is expedient by reason of serious risk of outbreak of small-pox or of other exceptional circumstances, require the guardians of any Poor law union to provide vaccination stations for the vaccination of children with glycerinated calf lymph, and modify as respects the area to which the order applies, and during the period for which it is in force, the provisions of this Act requiring the public vaccinator to visit the home of the child otherwise than on request of the parent."

General RUSSELL spoke in support of the clause.

Mr. CHANNING condemned it as another despotic attempt to override the local authority.

On a division the clause was adopted by 23 to 5 votes.

Mr. CARLILE moved to insert the following new clause, viz.:—"The Local Government Board shall make regulations to secure the provision and supply of glycerinated calf or other approved animal lymph and may license on such terms as the Board may think fit any person or body to supply such lymph."

Mr. CHAPLIN said the first part of the clause was unnecessary and the second imposed too heavy a responsibility on the Local Government Board.

Thereupon Mr. CARLILE withdrew his proposal.

Mr. CHANNING then moved to insert this clause, viz.:—"In all cases in which a duly registered medical practitioner shall certify in writing that vaccination is not running an ordinary course and that owing to supervening disease medical attendance is necessary the public vaccinator or any other duly registered medical practitioner practising in the district to whom the certificate may be brought by the parent or other person acting in respect of the child vaccinated shall either himself attend the case or obtain a qualified practitioner to attend the case without charge to the parent, and any reasonable charges in respect of such attendance shall be defrayed by the guardians and shall be a lawful expenditure from the rates."

Mr. CHAPLIN said he could not accept the clause. So far as public vaccinators were concerned it was unnecessary because the point was already provided for, while as to private vaccination it would make the boards of guardians responsible for the carelessness of a private practitioner.

Sir CHARLES DALRYMPLE said that while serving on the Royal Commission nothing impressed him more than the want of substantiality in the allegations with regard to terrible results from vaccination. Very few of them indeed stood the test of inquiry.

Sir WALTER FOSTER submitted that though the cases might be few that was no reason why such a clause as this should not be adopted, but on the contrary it was a reason for its adoption.

The Committee rejected the proposed clause by 21 to 8 votes.

On the motion of Mr. CHANNING a clause to the following effect was

Digitized by Google

inserted in the Bill, viz.: "Persons committed to prison on account of the non-compliance with any order or non-payment of fines or cost under the Vaccination Acts shall be treated in the same way as first-class misdemeanants."

Sir WALTER FOSTER moved to insert a new clause to this effect—viz.: "Every duly registered qualified medical practitioner not being a public vaccinator shall be entitled to be paid for each successful vaccination by the guardians of the union in which the vaccinated person usually resides a fee in accordance with the table of fees set forth in the second schedule to this Act, provided he send to the public vaccinator within four weeks after the date of the vaccination a certificate signed by him containing the following particulars: (1) the name and address of the vaccinated person and that the vaccination was successful; (2) the date when the vaccination was performed; (3) the date, not being less than eight or more than fourteen days after the date of the vaccination, when the patient was examined; (4) the number and area of the vesicles; (5) that the vaccinator claims no fee for the vaccination except the fee payable under this Act; and (6) such other particulars as may be prescribed. A medical practitioner who wilfully makes any untrue statement in any certificate under the last preceding section shall be liable on summary conviction to a fine not exceeding £20, or on conviction or indictment to a fine not exceeding £50.

Sir WILLIAM PRIESTLEY, Sir CHARLES CAMERON, and other members of the Committee spoke in support of the proposal.

Mr. CHAPLIN, however, resisted it, doing so mainly on the ground of the cost it involved and the want of supervision of the work done.

On a division the clause was rejected by 21 to 10 votes.

Mr. CHANNING moved to insert this clause: "When it has been determined by the verdict of a coroner's jury or by any court that death or injury has been caused to a child by vaccination or by any other disease directly originating in or provoked by vaccination the parent shall be entitled to obtain compensation from the board of guardians, and any such claim for compensation shall be determined by the judge of the county court, and any payment for such compensation shall be a lawful expenditure by the guardians out of the poor rate."

The clause was under discussion when the Committee adjourned.

The Committee met again on Tuesday, July 5th, with Sir HENRY CAMPBELL BANNERMAN in the chair, and completed the consideration of the Bill.

Discussion was resumed upon the new clause proposed at the last sitting by Mr. Channing to provide for compensation for death or injury caused by vaccination.

Mr. CHANNING said that he learned from the report of the Registrar-General for 1895 that the number of deaths officially certified to have been caused by cow-pox and other effects of vaccination was 785 from 1881 until 1895. He did not wish, he said, to cast aspersions upon the medical profession, but it was evident that where other diseases had supervened before vaccination it was probable that the later symptoms had been certified as the cause of death instead of vaccination itself. Members of the Committee must not lose sight of the fact that in this legislation they were giving a reward to the medical profession for carrying out this practice of vaccination, and in the circumstances he thought it was only right that there should be compensation in cases where negligence had brought about disastrous results.

Mr. LOGAN suggested that as so much power was being taken out of the hands of guardians the compensation should not be found by them but by the Imperial Treasury.

The proposed clause was rejected by 16 to 6 votes.

On the motion of Sir WILLIAM PRIESTLEY, acting on behalf of Sir WALTER FOSTER, the following new clause was inserted in the Bill, viz.:—"Any local authority may incur reasonable expense in the diffusion of information as to the reasons why vaccination of children is required by the State and of literature generally illustrative of the advantage of vaccination."

Sir WILLIAM PRIESTLEY moved to insert the following as a new clause, viz.:—"No proceedings under Section 31 of the Vaccination Act of 1867 shall be taken against any parent or person who has been convicted under Section 29 of the said Act on account of the same child until after it has reached the age of five years, and no such parent or person shall be liable to a penalty under the said Section if he satisfies the court that he conscientiously believes vaccination would be prejudicial to the health of the said child." His great object, he said, was to smooth the working of the scheme of the Bill and to minimise some points of objection to it. He was a believer in the efficacy of vaccination as a preventive of small-pox and he wished to see the benefits of it enjoyed by rich and poor to the very greatest extent possible. He had taken the age of five years because then the child might be expected to go to school, where, if it was unvaccinated, it became a source of danger to its fellow scholars. No one could forget the great object-lesson afforded by the case of Gloucester where the epidemic broke out in one of the schools and thence spread all over the town. He learned from the Vice-President of the Committee of Council on Education and from others that a great number of children were sent to school at an earlier age and therefore he was quite prepared to substitute four for five years. It might be said that his proposal was not logical but it was no more illogical than the scheme of the Bill and after all the country was not ruled by logic.

Colonel LONG pressed the Government to accept the clause in the interests of vaccination.

Mr. JOHNSON-FERGUSON said he was authorised to say on behalf of Sir Walter Foster that while he preferred his own amendment he would have voted for this clause if he had been able to be present.

Mr. HOBHOUSE spoke of the clause as a reasonable concession which the Government ought to make to public feeling on this subject.

Mr. CHAPLIN said he was surprised, after the long debate on Sir Walter Foster's amendment in a full Committee, that this clause should now be brought forward when the Committee was very poorly attended. He opposed the amendment and he opposed this clause because he believed they were not in the interest of vaccination. It was matter of notoriety that removals were frequent among the poorer classes and great difficulty was experienced in tracing them. With much trouble a considerable number of these removals had been traced in the past, but if this clause were carried, and if after tracing a removal with infinite pains, the officer was met with this plea of conscientious objection it was scarcely conceivable that thereafter he would devote much zeal or energy to the work of tracing removals. This, of course, was exactly what the anti-vaccinationists desired to bring about and consequently the clause played into their hands. The hon. Member had selected as the time for this escape from vaccination the time when the child went to school—the time when, on his own confession, the danger to the community began. Surely, he could not have fully considered the probable effect of his clause. He would only say that whatever might be the fortune of the Government in this thinly-attended Committee he could not accept the clause, and it would be his duty to resist it by every means in his power.

After further debate the clause was adopted by the Committee by 20 to 11 votes.

On the motion of Mr. MONK the age of four years was substituted for that of five years.

Mr. CHANNING moved to substitute for "if he satisfies the court" the words "if he makes a declaration," but the Committee rejected the motion by 23 to 6 votes.

Mr. LOGAN moved to insert a new clause to this effect, viz.:—"Nothing contained in this Act or in the Vaccination Acts of 1871 and 1874, or the Poor-law Amendment Act of 1842, shall empower the Local Government Board to make rules or regulations inconsistent with the spirit of this or any other Vaccination Act, and no rule or regulation now in force or made hereafter under the Vaccination Acts shall be regarded as giving the Local Government Board or any person or body of persons authority to direct an officer of a board of guardians to institute or conduct proceedings against any parent or guardian of a child for default under any Vaccination Act."

Mr. CHAPLIN declined to accept it, saying he must preserve all the powers given him by the existing law. He would not assume that boards of guardians would deliberately override the intentions of Parliament, but if any board did put itself in that position he would avail himself of the powers he possessed to enforce the fulfilment of the intentions of Parliament.

The clause was rejected by 22 to 10 votes.

Mr. STEADMAN moved this clause, viz.:—(1) In all cases of severe illness following vaccination the surgeon performing the operation shall be liable to an action for such damages as a jury may seem fit to assess, as in any other case of malpractice; and (2) in case death follows as a consequence of vaccination, the same being affirmed either on the medical certificate of death or by the verdict of a coroner's jury, the surgeon performing the operation shall take his trial for manslaughter.

The ATTORNEY-GENERAL (Sir RICHARD WEBSTER) said that such a clause was altogether out of the question.

After a short debate Mr. STEADMAN withdrew the clause.

On the motion of Mr. HAZELL the following clause was inserted in the Bill, viz.:—"The clerk of any sanitary authority which shall maintain a hospital for the treatment of small-pox patients shall keep a list of the names, addresses, and condition as to vaccination of all small-pox patients treated in the hospital, such entries to be made on admission, and shall at all reasonable times allow searches to be made therein, and upon demand give a copy under his hand or under that of his deputy of every entry in the same on payment of a fee of 6d. for each search and 3d. for each copy."

Mr. BRIGG moved, but afterwards withdrew, these two clauses, viz.:—"The Local Government Board shall issue all lymph marked in such a way as will clearly show its place of origin, and any parent or guardian may require to be shown the unbroken distinctive mark on the capsules, bottle, glass points, or other article used for containing the lymph, before allowing the lymph to be used for vaccinating his child." "The medical officer of health for the district shall, on payment of 1s. to him, furnish a certificate of fitness or non-fitness of any child presented him for the operation of vaccination."

Mr. CHANNING moved to insert: "Where the parent of any child in respect of whom proceedings are taken under the Vaccination Acts proves that any other of his children has died or suffered serious illness owing to vaccination, such proof shall be held to be a reasonable excuse for the purposes of Section 29 of the Act of 1867."

Mr. CHAPLIN undertook to consider the point raised here before the report stage.

On the strength of this undertaking Mr. CHANNING withdrew the clause.

The amendments on the notice paper having now been exhausted the motion was put from the chair and agreed to that the Bill as amended be reported to the House.

SATURDAY (16th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.), London Throat Hospital (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

WEDNESDAY (13th).—DERMATOLOGICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—5.15 P.M. **Clinical Meeting.** LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—5 P.M. **Special Meeting to discuss whether it is desirable (1) to Limit the Membership of the Society; and (2) to Alter the Days of Meeting.**

THURSDAY (14th).—BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. **Adjourned Discussion on Mr. S. Keith and Dr. Bantock's papers on Dysmenorrhœa. Specimens:—Mr. B. Jessett: (1) Carcinoma Uteri removed by Vaginal Hysterectomy, Recovery; (2) Carcinoma Uteri with Fibroids, Vaginal Hysterectomy, Recovery; (3) Double Pyo-salpinx with Broad Ligament Cyst, Operation, Recovery. Papers:—The President: Two unusually interesting Cases of Ovarian Cystoma (with specimens)—Mr. C. Martin (Birmingham): Some Moot Points in the After-Treatment of Cases of Abdominal Section.**

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

TUESDAY (12th).—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. **Dr. Colman: Lecture.** WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM (73, Welbeck-street).—4.30 P.M. **Dr. F. Beach: On Mental Disorders in Children, with cases.** CITY ORTHOPÆDIC HOSPITAL.—5.30 P.M. **Mr. J. J. Clarke: Deformities caused by Badly-shaped Boots.**

WEDNESDAY (13th).—WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. **Dr. P. S. Abraham: Dermatological Cases.**

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1898, which was completed with the issue of June 25th, and the Title-page to the Volume were given in THE LANCET of July 2nd.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1898 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance.

THE AVENGING DRUGGIST.

A CASE has recently been before a provincial police-court which is not without its amusing side, though that side may be obscured to the view of the plaintiff and the defendant. A small boy persisted in

Digitized by Google

swinging on the supports to the blinds of a druggist's shop. The druggist dosed him with quassia in solution as a punishment. The small boy "had the law of" the druggist who, as a result, had to pay a fine. Our sympathies are all with the druggist, but yet we think the decision of the case against him was right as well as a foregone conclusion. He should have spanked the boy, whose outside would certainly not have been regarded either by magistrate, parent, or public as so clearly sacred from interference as his gastro-intestinal tract. The ingenuity of the punishment was bound to inflame general sentiment against him, even while no one may deny that the boy's behaviour was aggravating. We think the magistrates were right to inflict a fine and hope that the decision will act as a deterrent for two rather obvious reasons. Firstly, if such retaliatory measures were to be sanctioned by law the next solution administered in this way might not be so harmless as quassia, the punishment might not fit the crime so well, and the executioner might be less instructed in therapeutics. Secondly, an element in this way is imported into punishment which should never be present in the punishment of children at any rate—the element of nervous terror. We know, and the druggist knew, that the solution of quassia was as harmless as, say, many sorts of table beer, but the boy did not know it. He might easily believe that his disagreeable sensations were the prelude to impending death from poisoning and a fond mother might possibly support the view, with the result that much more pain, and of a different sort, would be caused than was intended.

THE ETIQUETTE OF CONSULTING PRACTICE.

To the Editors of THE LANCET.

SIRS,—I am the only medical officer in a wide rural parish fifteen miles from a small town of over 5000 inhabitants in which are four medical men, including the one with whom my relations have become strained. The third party referred to below is the agent of the squire whose servants are the patients. 1. Is it usual or right for a consultant to come and see a patient without first relatives and medical attendant agreeing that such a step was necessary? 2. Is it usual or right for the consultant to prescribe new medicines and new treatment when relatives go to him privately after consultant and attendant have already agreed upon the course of treatment? 3. Is it usual or right for a consultant to write to a third party and explain a case when he has changed his mind regarding it and not do so to the medical attendant in the first instance? 4. Is it usual or right for a consultant to come more than once to see a case at the request of a third party without the consent or approval of the medical attendant when the case is not an urgent one? 5. How should I act in future towards this consultant?

I am, Sirs, yours faithfully,

July 4th, 1898. M.D.

*** Our correspondent will understand that we have only his side of the case before us and that we are not in possession of any of the special circumstances. Speaking generally:—1. It is usual and right that the medical attendant in charge of the case should be informed of the desire for a consultation. 2. and 3. It is usual and right that the consultant should communicate his views with regard to any change of diagnosis or treatment to the medical attendant in charge. 4. This question is not quite clear. If it is irregular for the consultant to see the patient at all without communicating with the medical attendant it is certainly wrong to continue to see the patient. 5. We must leave this point to our correspondent, having given our replies to his first three questions.—ED. L.

A MUNICH "M.D." IN THE CORONER'S COURT.

MR. KING HOUCHIN, deputy coroner for East London, held an inquiry on Tuesday last at the Vestry Hill, Bancroft-road, Mile-end, into the circumstances attending the death of the nine months old female child of Mrs. Annie Bernard of 7, Newman-street, the wife of a Hebrew teacher. From the mother's evidence it appeared that on June 19th the child seemed to be sickening for the measles. She sent for Dr. Jones, but he did not come himself, his assistant attending who ordered the child to be put into a hot bath. She was afraid to carry out this direction because she thought the assistant looked so young and she did not care to take his advice. She then sent for Dr. Wolpe, who came and prescribed. On Saturday the child seemed worse and Dr. Wolpe again attended and prescribed. She afterwards became worse and witness sent for Dr. Jones of Finsbury-square, not the same Dr. Jones whom she had previously sent for, but as this gentlemen was unable to come her husband sent for Mr. Ambrose. Mr. Ambrose gave no hope and the child died at 4 o'clock in the afternoon.—The coroner: Did she come out in a rash? Witness: Yes sir, all over the body.—Achille Wolpe, 2a, St. Mark-street, Goodman-street, E., said he was a medical practitioner.—The coroner: What is your qualification? Witness: I am M.D. of Munich; I was told another doctor had been attending and had ordered a hot bath for the child.—The coroner: How was it you took the case out of his hands? Witness: I know nothing about him at all.—Coroner: May I inquire how it is you practise at all? Witness: I want to pass my examinations here and as far as I understand the law of this country it does not prohibit my practising as such, but it prohibits my recovering my fees in a court of law.—The Coroner: But you misunderstand the law of this country, for you render yourself liable every time you visit or prescribe. You render yourself liable to a prosecution because you are not qualified. Witness: The law does not prohibit my practising as such; I do not wish to dispute, but I have read the law.—The Coroner: There is a letter from you advising the mother to call in another doctor when you saw the child was likely to die. You then advised her to call in a gentleman who has a recognised qualification and you advised Mrs. Bernard to call in Dr. Jones again as you would be unable to certify the cause of death. This places the public in a false position, and how is the public to be protected if individuals like yourself attend cases and then if the patients are near death step out of the way and advise the calling in of another doctor? Witness: I did it in order to save an inquest.—The Coroner: Well, you see, you have not accomplished your object for here is the inquest. What was the child, in your opinion, suffering from? Witness: Measles, complicated by bronchitis.—The Coroner: I do not for a moment dispute your ability, but you are placing yourself within the reach of the law. Witness: I have tried to inform myself on the question and have been told the law does not prohibit my practising.—The Coroner: But you want to get your fees, don't you? Witness: That is my look-out.—The Coroner: I suppose you don't tell everybody you are not qualified? Witness: If I am asked I should certainly say I was not qualified in England.—Mr. Robert Ambrose, 1, The Mount, Whitechapel, said the child was dying when he saw her from congestion of the lungs and measles. There were more children upstairs suffering from measles.—In summing up the case the coroner said he should feel it his duty to inform the proper authorities so that this gentleman might be prosecuted. He had no English qualification and sailed under false colours, thereby deceiving the public. The woman (Mrs. Bernard) had no knowledge that he was not qualified. He accepted the position and then he told the mother she had better call in another doctor. In his note to the coroner Dr. Wolpe stated that he advised the mother to call in another doctor because he could not certify the death himself. In returning a verdict of "Death from natural causes" the jury expressed a wish that the coroner would act in the manner which he had indicated.

AN APPEAL ON BEHALF OF THE WIDOW OF THE LATE JAMES McGREGOR LAING.

To the Editors of THE LANCET.

"THE TREATMENT OF SEA-SICKNESS."

To the Editors of THE LANCET.

SIRS,—I have ventured to forward the following remarks in the hope that they may be useful to "M.R.C.S., &c.," whose letter was published in THE LANCET of June 25th.

The treatment of sea-sickness—speaking from an experience of nearly five years in the North Atlantic passenger trade—does not usually give very satisfactory results. We have no means either by

Digitized by Google

drugs or otherwise of controlling it, and something which one voyage materially palliates or "cures" the patient will often utterly fail him in his next trip. The nausea and subsequent vomiting of the first few hours are to a passenger prone to this malady almost inevitable but seldom require interference, though the retching may become distressingly violent and, if accompanied by streaks of hæmorrhage, especially alarming to the patient. I have found that the best way of relieving this condition is to apply a mustard leaf to the epigastrium, to give a hypodermic injection of morphia, some crushed ice to suck, and to insist on the recumbent position being maintained by the patient. A whiff of amyl nitrite or chloroform is often useful; alcohol is best avoided, though a little iced champagne may be sipped in very small quantities. The frequently present constipation must be relieved by an enema or suppository—preferably a glycerine "enule" (B. W. & Co.)—as purgatives by the mouth will usually be quickly rejected. Too much must not, however, be expected of this or any other line of treatment, but the urgency of the symptoms usually abates in from twelve to forty-eight hours, the patient gradually acquiring that stability of the nervous system nautically termed "getting his sea legs." The cases of prolonged nausea and sea-sickness in which the patient refuses or rejects all food are very trying both to the invalid and to the surgeon. If the cabin is a fairly large one as cabins go, is efficiently ventilated, and is not crowded I think these cases do better in their berths than on deck—I am speaking of the North Atlantic, in which trade the weather is generally cold—though meddlesome friends will urge them to go on deck, to "walk about," and to "fight against" the malady. This unequal combat generally ends in the victory of Father Neptune, and the vanquished one staggers or is carried below sick, blue with cold, and generally wretched. Hot bottles, blankets, a little stimulant—hot beef-tea—will quickly make the patient more comfortable. For general fluid nourishment I use Valentine's, Wyeth beef-juice, or Brand's essence, and these will frequently be retained, especially if the first two are mixed previously with a little powdered ice and administered in teaspoonful doses. If they are rejected they should be given again directly the fit of vomiting is over. As regards drugs I used with considerable success a prescription of chloroform, nux vomica, and compound tincture of lavender recommended by Mr. Barber of the P. & O. Service. An alkaline stomachic mixture with nux vomica is also useful after the acute symptoms have vanished; it assists a languid or capricious appetite. A dose of bromide of potassium and chloral or a hypodermic injection of morphia is beneficial at night, allaying restlessness and procuring sleep. In those cases which essay—with more or less success—the ordinary saloon fare anything in reason may be allowed them. One woman insisted that "sauerkraut" was the only thing which would relieve her, and it certainly on the trip in question seemed to stop the sickness, though it failed to do so on a subsequent one. Among adults there are some who without any vomiting or nausea suffer from persistent and severe headache and others who suffer from continuous intense giddiness (I am not speaking of the ordinary, generally temporary, vertigo associated with vomiting); the former may derive benefit from phenacetin and caffein, bromide and chloral, or from nitroglycerine. The discomfort of the latter is only alleviated by the maintenance of the horizontal position. In both the bowels must be attended to, and the appetite stimulated by a stomachic mixture. Children rarely suffer severely from sea-sickness, they are sick for a few hours and then are soon running about, though in one case, I remember, a neurotic girl some eleven or twelve years of age, after some four or five days of not very acute vomiting, suffered severely from tetany. A gentle laxative to combat the costiveness usually induced in them by a sea voyage and a little bromide and chloral at night will soon put them right, as a rule. My voyages have never lasted longer than ten days, so that in the case of longer trips one's experience might probably be greatly modified. I have never seen the numerous "quack" remedies do the slightest good, nor have I ever seen the at one time much vaunted "chlorobrom" retained where bromides of potassium and chloral where rejected by the stomach. In conclusion, I would say that a farewell dinner or other jollification the day before commencing a sea voyage is to a person subject to sea-sickness the very worst possible preparation for it. A blue pill followed by a Seidlitz powder is far better, though certainly not so festive.

I am, Sirs, yours faithfully,

HUGH TAYLOR, M.A., M.B. Cantab.

Southampton, June 27th, 1898.

AN IMPORTANT QUESTION.

To the Editors of THE LANCET.

SIRS,—I attended a woman in her confinement on June 1st. Delivery occurred before my arrival and I had only to remove the placenta, which was easily expelled. Puerperal fever set in *immediately* and the patient died on the 13th. Would you be so kind as to inform me when I could safely attend another confinement?

I am, Sirs, yours faithfully,

M R C.S.

*** There is no definite time after the lapse of which our correspondent can be perfectly safe, but he may attend another confinement so soon as he is "aseptic." There are three ways in which he might infect another case: (1) by his hands; (2) by his clothes; and (3) by his instruments. His hands are probably no longer septic from the case which died, but they should be thoroughly cleansed before every case by washing not only with soap and water but with antiseptic solutions, and by paying especial care to cleansing beneath the nails. For details of such ablution we refer our correspondent to all modern text-books of midwifery. Every midwifery case should be looked on as an operation in which the wound very easily becomes affected with sepsis. The clothes in which the patient was attended should be thrown away or, if that be undesirable, they should be disinfected thoroughly by heat. The cuffs of the sleeves very easily get septic. It would certainly be well never to wear the coat again. The instruments are very important; all those of metal, such as scissors used for cutting the cord and forceps, should be well boiled. Catheters should be burnt and the whole midwifery bag, including the bottles, should be rendered aseptic. The lining of the bag especially and the handle are very liable to transmit sepsis and it is well to have a new lining. These directions may appear extravagant and absurd, but it is useless to trust to the mere lapse of time. Puerperal fever is always caused by the transference of micro-organisms and it is possible with care for the accoucheur to be quite sure that his hands and all the instruments he uses are quite free from germs. This care is well repaid, not merely by absence of the grosser forms of sepsis, such as puerperal fever, but by the non-occurrence of slighter septic affections such as pelvic cellulitis and "white leg."—ED. L.

PREJUDICE.

MR. H. K. HUNTER, L.S.A., who was recently fined £5 at the instance of the General Medical Council for using the title of physician, has soon found out that the Council's much criticised action has been of serious import to him. He had occasion recently to sue a man in the county-court and was then told by the county-court judge that the fact that he had been fined in this manner (the circumstances were commented upon in THE LANCET of April 16th) would "make a great difference" to his case. We quote from the *Cambridge Express*. This was certainly frank of the judge, but was it just?

M.A. Cant., M.B.—1. There are many Anglo-Chinese and Franco-Chinese dictionaries, grammars, and manuals of conversation, but some are very expensive and others are unreliable. Our correspondent might try "The Grammar of Colloquial Chinese" (second edition, corrected), by J. Edkins; "Chinese without a Teacher," by H. Giles; and "Select Phrases in Canton Dialect," by W. Lobscheid. Concerning the prices and publishers of these books he must consult a bookseller. Possibly he can get access to a library where he could see Morrison's valuable dictionary. 2. Dr. David Walsh's "Medical Work on the X Rays," the French x ray journal published by Messrs. Baillière, Tindall, and Cox, and a bibliography of x ray work by Mr. C. E. Phillips might also be consulted.

Mr. Percy Gosney.—Our correspondent will allow that what the natives said does not amount to good evidence. It is possible that they have discovered as much as Professor Schenck has discovered, but their inability to divulge the secret makes their position a very weak one.

Subscriber is referred to the Rules in Lunacy for 1892 and 1893 for the reply to his question. We cannot give a general answer. The Masters in Lunacy would be the ultimate judges of any difference of opinion between the Commissioners and a committee.

M.B. (Lond.) does not state in his letter the sum which could be paid for the patient each week. He should also in any further communication give an address to which answers might be sent.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received: *Manchester Guardian, Birmingham Gazette, Hereford Times, Beverley Guardian, Suffolk Chronicle, Herald of Wales, Builder, Scotsman, Citizen, Dundee Advertiser, Bath Chronicle, Worcester Echo, Eastern Morning News, Times of India, Pioneer Mail, Western Morning News, Salisbury Journal, Bournemouth Observer, Architect, Peeblesshire Observer, Liverpool Daily Post, Carnarvon Herald, Eastbourne Chronicle, Buxton Advertiser, High Peak News, Leeds Mercury, Brighton Argus, Leicester Post, Sheffield Daily Telegraph, Sussex Daily News, Newark Advertiser, Cheshire Observer, Halifax Guardian, Barnsley Independent, Luton Reporter, Newcastle Weekly Chronicle, Kentish Observer, Glasgow Herald, Yorkshire Post, Bristol Mercury, Brighton Gazette, Sanitary Record, Reading Mercury, City Press, Cambrian News, Local Government Chronicle, Mining Journal, Carlisle Patriot, Carlisle Journal, Surrey Advertiser, Local Government Journal, Hertfordshire Mercury, Shrewsbury Chronicle, Dunstable Borough Gazette, Poole Herald, Birmingham Daily Post, Langton Weekly Herald, Public Health, West Middlesex Herald, Woolwich Gazette, Spalding Guardian, Peterborough Express, &c., &c.*

THE

"Allenburys" Foods

FOR

TRADE MARK. A.D. 1715.

Infant Feeding

A PROGRESSIVE SERIES OF FOODS.

The Foods constituting the series described below are not interchangeable, but should be used in succession as indicated. Perfectly sterile in themselves, they are best given with the "Allenburys" Feeder, which is capable of easy and complete sterilization, thus presenting a physiologically accurate diet, free from all fear of contamination by the products of decomposition.

THE

"Allenburys" Milk Food No. 1

Affords, when prepared for use, a correct substitute for human milk. It is manufactured from fresh cow's milk, so modified as to present all the constituents of human milk in their true relative proportions. Being in a desiccated and sterilized form, it requires only the addition of *boiled* water to obtain a pure and sterile food suitable for infants during the first three months of life.

THE

"Allenburys" Milk Food No. 2

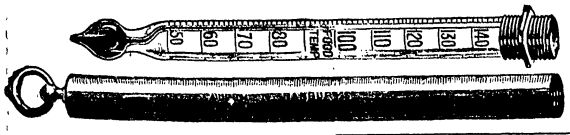
Is identical with No. 1, with the addition of small quantities of maltose, dextrine, and soluble phosphates derived from the digestion of whole meal with Malt Extract. These ingredients are a valuable adjunct to the increasing needs of digestion, yet the Food is readily and easily assimilated, there being no unconverted starch present. The No. 2 Food is designed for children between three and six months of age.

THE

"Allenburys" Malted Food, No. 3,

USUALLY KNOWN AS

Allen & Hanburys' Malted Infants' Food,



Is not a *milk*, but a purely *farinaceous* Food, prepared by improved methods after Baron von LIEBIG'S formula. The basis is fine wheaten flour, which has been thoroughly cooked and partially digested by an active Malt Extract, so that a large proportion, but not all of the starch has been converted. It is particularly rich in soluble phosphates and albumenoids.

This Food should be given from six months and upwards. For the first month or so after the change of diet it is generally advisable, instead of using cow's milk, to employ the "ALLENBURYS" MILK FOOD No. 1 or No. 2 in preparing it. The demand on the child's digestive organs is less abrupt, and a humanized milk is used in place of the more indigestible cow's milk. This precaution is specially recommended in the case of delicate children.

The "Allenburys" Feeder.

This bottle has the nipple at one end and a valve-stopper at the other, so that, both being removed, it can readily be cleansed under the tap. The valve admits air behind the column of milk, thus avoiding the swallowing of air and the resulting wind-colic; while the rubber nipple is easily detached, and can be turned inside out. The bottle is graduated approximately in ounces. Price 1/- each.

The "Allenburys" Thermometer, in nickel case, as figured, is provided for determining the right temperature at which the Foods should be given, and for general Nursery use. 1/- each.

Allen & Hanburys Ltd., Plough Court, Lombard Street, London.

Infants' Food Manufactory: WARE MILLS, HERTFORDSHIRE.

☛ **For further details concerning these Foods, see succeeding numbers of the** *British Medical Journal* **and** *Lancet.*

"APENTA"

THE BEST NATURAL APERIENT WATER.

APENTA WATER IN THE TREATMENT OF OBESITY.

"The *Berliner Klinische Wochenschrift* for March 22nd, 1897, speaking of some experiments made under Professor Gerhardt's direction in the Charité Hospital as to the value of Apenta water in the treatment of obesity, says that such experiments could not be carried out until quite recently, on account of the inconstant composition of the bitter waters coming into the market. In this respect, the Apenta water is favourably circumstanced, and it was chosen for these observations because of its constancy of composition. The conclusions arrived at as to the value of Apenta in the treatment of obesity, and as to its influence on tissue-change, were that it succeeded in producing a reduction of fat in the body without detriment to the existing albumen, and that the general health of the patient suffered in no wise, and the cure ran its course in a satisfactory manner."—NEW YORK MEDICAL JOURNAL, Feb. 5th, 1898.

"REGIMEN FOR THE OBESE." Cards forwarded to the MEDICAL PROFESSION on application to

THE APOLLINARIS CO., LTD., 4, STRATFORD PL., LONDON, W.

HARVEY'S
SUGAR-FREE PALE ALE

(Protected by Her Majesty's Royal Letters Patent).

The only **ALE** which may be drunk with impunity by persons with whom, from various causes, ordinary Beer does not agree.

ABSOLUTELY FREE FROM SUGAR.

Mr. T. FAIRLEY, Leeds City and County Analyst, F.R.S.Edin., F.C.S., F.I.C., certifies, June 3rd, 1896, that this Pale Ale is

"ABSOLUTELY FREE FROM FERMENTABLE SUGAR."

For further analyses see THE LANCET, May 22nd, 1897, and the BRITISH MEDICAL JOURNAL, April 24th, 1897.

An article in THE LANCET says: "For years I have been unable to take beer as a beverage on account of the lethargy, indigestion, pain, and stiffness which invariably followed such indulgence; but for three months continuously I have taken one glass of this Sugar-free Pale Ale at luncheon without the slightest 'rheumatic' effects."
—THE LANCET, August 14th, 1897.

SPECIAL TERMS allowed to the Medical Profession, to whom a SAMPLE BOTTLE will be sent FREE on application.

The Sugar-free Pale Ale is supplied, upon receipt of cheque or postal order, in Imperial Half-pints, price **3s. 9d.** per dozen; Reputed Pints, **5s. 0d.** per dozen.

MOUNTJOY BREWERY, LTD.

(Late FINDLATER & CO.),

RUSSELL STREET, DUBLIN.

NOURISHING STOUT.

THE attention of Medical Men is respectfully called to the value of this finest of Malt drinks as a valuable Tonic Restorative. Numerous Unsolicited Testimonials have been received by our Bottlers all over England.

SAMPLES will be sent direct from the BREWERY, Carriage Paid, with name of nearest Bottlers, on application.

ANALYTICAL RECORD FROM "THE LANCET."

"CROWN STOUT.—MOUNTJOY BREWERY, RUSSELL STREET, DUBLIN.

"The nourishing qualities of Stout are due mainly to a comparatively high proportion of Malt extractions, which, consisting principally of maltose and dextrine, offer little task to the digestive organs. The sample before us is marked by an excellent proportion of these extractions, while, at the same time, the alcoholic strength is by no means excessive.

"The results of analysis were as follows: Malt extractions, 9 0 per cent.; mineral matter, 1·38 per cent.; alcohol—by weight 4·62 per cent., by volume 5·78 per cent.; equal to proof spirit 10·13 per cent. The mineral matters consisted almost entirely of soluble potassium phosphate. The Stout was in good condition, ripe, yet free from undue acidity, and possessed a characteristic malty flavour."

SIR CHARLES CAMERON'S ANALYSIS.

"DUBLIN.

"I have analysed a specimen of **Nourishing Dublin Stout**, submitted to me for that purpose by **The Mountjoy Brewery, Dublin.** I have never examined a specimen of Porter in which the solid or nutritive constituents were so abundant as in the case of this Stout. It contains **Ten Per Cent.** of its weight of solid matter, or nearly the amount of solids contained in milk. Its flavour is good, and it is **Remarkably Free from Acidity.**

"CHARLES A. CAMERON,

"Professor of Chemistry, College of Surgeons, Dublin."

PROFESSOR TICHBORNE'S ANALYSIS.

"DUBLIN.

"I have examined and analysed for several years the Stouts brewed by **The Mountjoy Brewery**—viz, **Single, Extra,** and their speciality known as **Nourishing** or **Crown** Stout. The gravities of all these Stouts are very high, as proved by my analysis. **The Crown** or **Nourishing** Stout gave me one of the highest gravities I have ever seen in Stout. They are all of first-class quality. **The Nourishing** Stout being exceptionally fine, and owing to its **strength** and **purity,** is a most valuable food for **Invalids.** They are all brewed from **Malt** and **Hops only,** the water used being the best brewing water the City of Dublin affords.

"CHARLES R. C. TICHBORNE,

"Professor of Chemistry, Dublin."

Re PHENACETINE.

IMPORTANT WARNING to MEDICAL MEN.

As discoverers and original makers of this **safe and valuable antipyretic,** we consider it to be our duty to **warn** the Medical Profession that an adulterated substance is now on the market, and is being sold as genuine Phenacetine. (*Vide* current Chemical and Pharmaceutical periodicals.) Our name is so well known in connexion with this product, that, for our reputation's sake, we are compelled to issue this notice.

Medical Men can protect themselves and their patients, and can rely upon obtaining a thoroughly pure product by adding the name BAYER when prescribing Phenacetine.

PHENACETINE-BAYER

is the pure and original product: the name is a guarantee of purity. Phenacetine-Bayer is put up in 4, 5, 8, and 16 grain Tablets, as well as in the Powder and Crystal form.

Samples and Literature can be obtained on application to the Wholesale Depots for all Bayer's Pharmaceutical Specialties—

ELBERFELD FARBEN FABRIKEN CO., Ld., 19, St. Dunstan's Hill, LONDON, E.C.

Also at MANCHESTER, GLASGOW, and BRADFORD.

GLYCEROPHOSPHATE ROBIN

Admitted in the Paris Hospitals

The Glycerophosphate Products of M. Robin were the first employed in therapeutics patented in 1887 and 1891.

Fac simile of the bottle reduced to the fourth.

NOTICE

We have adhered to the principle of preparing nothing but the **GLYCEROPHOSPHATE** of **LIME** chemically pure, a salt which answers per excellence to the requirements of glycerophosphated medications.

We add to this a small proportion of Glycerophosphate of soda in order to increase its solubility. We consider as irrational the addition of salts based on potash, magnesia, iron, etc., which enter in important proportions in the constitution of the organism and which might even counteract the influence of the Glycerophosphate by reducing its solubility.

Our sole aim is to offer to the medical fraternity a product offering all the necessary guarantees :

1° of a complete solubility without the addition of foreign acids;
2° of an easy administration even to children;
3° of an undoubted beneficial effect against :

Rickets in Children, Weakness of the **organism, Neurasthenie, Neuralgia, Phosphaturie, Debility** during **pregnancy, Weakness of the nervous System,** etc.

The numerous testimonies of the medical fraternity in favour of the granulated **Glycerophosphate** of **M. Robin** have confirmed the value of the preparation.

ORDINARY DOSE 2 or 3 measures for an adult just before the two principal meals, and 1 or 2 for children in a little water or milk.

Spoon for measuring is delivered with the bottle.

We also prepare **injectable Glycerophosphate** *each ampulla contains 20 centigrammes per cubic centimeter of sterilised* **Glycerophosphate of Soda.**

PRESCRIBED THE WORLD OVER BY THE ENTIRE MEDICAL PROFESSION.

Samples free to Doctors on application.

WHOLESALE : 13, Rue de Poissy, PARIS.

AGENCY : **London, JOZEAU, 49, Haymarket, W.**

ARMOUR'S

NUTRIENT WINE

OF

BEEF PEPTONE.

In 8-oz. and 16-oz. Bottles.

An elegant and acceptable form of Pre-digested Food, with the stimulants of both Beef and Wine. Peptone, prepared from selected fresh Beef, artificially digested by Pancreatin, is the basis of this Wine. The familiar preparations known as Beef, Wine, and Iron are of undoubted value as tonics, but are entirely devoid of the very essential constituents which ARMOUR'S Nutrient Wine possesses—namely, NUTRITION.

ARMOUR & COMPANY will be pleased to send Samples to Physicians on application, and beg to respectfully request that, when prescribing, "ARMOUR'S" may be indicated.

ARMOUR & COMPANY (Chicago), London, S.E.

COX'S TASTELESS PILLS

Our Mr. Cox invented PEARL COATING to render Pills TASTELESS more than fifty years ago.

THE PATENT WAS DATED AND SEALED APRIL 13th, 1854.

Of course success like this has produced the inevitable copyist; our prices, however, will be found to compare most favourably with any makers where best drugs and chemicals are used, and we pay all carriage and postage.

In order to secure our goods, and to avoid the possibility of others being substituted, please see that all packages bear our name and trade mark.

Our JULY, 1898, Catalogue, containing over 800 formulæ, including the most approved new remedies suitable for pilular form, post free (with samples if required) upon application.

N.B.—We make and sell nothing but Pills.

ARTHUR H. COX & CO., BRIGHTON.

A new Silver Preparation, highly efficacious in the treatment of Gonorrhœa, and most strongly recommended as an Antiseptic Wound Healer. PROTARGOL contains 8 per cent. of silver, and is easily soluble in cold or warm water, is non-irritating, and possesses a better penetrating effect on the tissues than any other known silver preparation. PROTARGOL is a chemical compound of silver and a protein substance. Its solution is not precipitated by albumen, chloride of sodium, or diluted hydrochloric acid.

PROTARGOL.

Dr. BENARIO, of Frankfort, declares that PROTARGOL possesses high bactericidal properties, and is therefore excellent for the treatment of Wounds. Professor NEISSER, of Breslau, states his opinion that PROTARGOL is the best, the safest, and the quickest remedy he has yet employed in the treatment of Gonorrhœa. An eminent surgeon, in "THE PRACTITIONER" for March, confirms, so far as his experiences go, the favourable opinion expressed by NEISSER, especially with reference to its powerful anti-bactericidal properties. The usual strength of the solution for injection is ½ to 2 per cent.

SAMPLES and LITERATURE can be had on application to the Wholesale Depôts for all Bayer's Drug Specialities—

ELBERFELD FARBEN FABRIKEN CO., Ltd., 19, St. Dunstan's Hill, London, E.C.

A Clinical Lecture
ON
FRACTURE OF THE NECK OF THE FEMUR IN CHILDHOOD.

Delivered at the Melbourne Hospital for Sick Children

BY R. HAMILTON RUSSELL, F.R.C.S. ENG.,
SURGEON TO THE HOSPITAL.

GENTLEMEN,—I have two cases of injury to the hip in young children to bring before you; the contrasting of the two is important. The first is a little girl, aged four years, brought to me in the out-patient room a few days ago with the following history. She was perfectly well until a month ago, when she fell from a gate on to the pavement and hurt the right hip. Since then the child has been limping and the limping and pain are becoming worse. The pain is much worse at night. Let me here remark that this history may or may not be of importance, it may or may not be trustworthy, for the poor, hard-worked mother can hardly be expected to be an accurate clinical observer and the insidious signs of early hip disease may easily have been overlooked by her before the accident. If this were so the blow on the hip, even though a trivial one, might easily light up the smouldering mischief and thus impart to the mother's mind a false notion as to the severity of the injury and as to the relationship between the injury and the present condition of lameness and suffering. The weight which the history will have with us then will depend largely upon the result of the physical examination which we proceed to make now. Stripped of all clothing it is seen that the child stands with the right thigh slightly flexed upon the pelvis, the knee bent, the heel raised from the ground so that the limb is resting on the forepart of the sole; there is also distinct eversion of the limb. On laying the child on her back the position of slight flexion, abduction, and eversion is maintained, while on inspecting the buttocks we find on the affected side partial obliteration and marked dropping of the gluteal fold; any attempt at free passive movement of the joint in any direction is vigorously resisted. Thus we have presented to us a clinical picture with which we are very familiar indeed, but the most important investigations have yet to come. In a paper published last year on the Early Diagnosis of Hip-joint Disease[1] I dwelt upon the enormous difficulties which may encompass the diagnosis of hip disease in its earliest stages, pointing out that this is due to the seemingly capricious way in which what are called the cardinal signs and symptoms may be conspicuously absent. Thus a child may be presented with a limp and with no pain; or, on the other hand, he may come with complaints of pain and without any limp. In either case there may be a complete absence of any alteration of the gluteal fold or limitation of movement of the joint or local tenderness. Thus it is not surprising that the error of overlooking hip disease in a very early stage is one of extreme frequency; in fact, it appears to me to be in certain cases practically unavoidable. I stated in the paper alluded to that so far as my own personal experience had served me there was only one sign which I had never found to be grievously misleading on occasions, but that I was quite prepared to find that it also would some day prove treacherous. The sign I refer to is general muscular wasting of the suspected limb or, rather, I should perhaps say, the absence of such wasting—for I must not be misunderstood as saying that wasting is a proof of hip disease or any other tuberculous lesion. Such a statement would be obviously absurd, for wasting may occur in various other conditions, some of which—notably certain examples of infantile paralysis—are very prone to be confused with hip disease. The presence of wasting in a suspected case can never be more than confirmatory of other evidences of hip disease, but its absence is a feature of supreme significance in guiding us towards a correct diagnosis. Thus I should say in respect of such a case if wasting is present the case may or may not be hip disease; if wasting is altogether absent, however, I believe we might safely conclude that the case is not hip disease. I repeat that it is the absence, not the presence, of wasting which is of such high diagnostic value. The method we adopt for estimating the wasting is repeated circumferential measurement of the limb at various corresponding levels with a tape measure. Certain obvious precautions must, of course, be taken, the limbs must be placed in exactly similar positions, the levels at which the measurements are taken must be accurately corresponding and the same individual must make the measurements in both limbs. In addition to the thigh, measurement of the calf is most important and usually affords the most satisfactory evidence of all. A veil of mystery still hides from us the true explanation of the wasting so universally associated with tuberculous disease; of one thing only may we be quite certain, which is that such wasting is a thing quite distinct from wasting due to disuse. I could desire no better illustration of the truth of this statement than is afforded by a comparison of our two cases.

CASE 1.—Measurement in this case disclosed distinct general wasting of the injured limb, but no alteration in length; it was regarded as a case of hip-disease and was treated as such.

CASE 2.—The patient is a little girl, aged three years, who is under the care of my colleague, Dr. Jeffreys Wood. She comes with a very similar history to that which we have just heard. About six weeks ago she had a fall on the hip and has been quite lame ever since—in fact, she refuses to make any attempt to walk. Many of her symptoms are similar to those of the first child. Thus she resents any movement of the right hip; she lies with it more or less flexed and always everted and there is marked dropping and diminution of the gluteal fold. She, however, has no marked pain at night, while the tendency to flexion does not seem to be insurmountable as in the first case, but the leg can be quite straightened although the eversion persists. The tape-measure, however, affords striking information, for we find on measuring the calves that there is no wasting of the affected leg whatsoever, while in the case of the thighs there is a slight disparity, but it is actually in favour of the injured limb.[2] On measuring now the length of the two limbs from the anterior superior spine to the inner malleolus we find that the affected limb is shortened by half an inch, and a further scrutiny easily makes it clear that the shortening is in the neck of the bone and that the trochanter is raised half an inch above Nélaton's line. Now it is quite true that this sign is commonly produced in hip disease by a process of absorption, but it is obvious that we may exclude any such consideration here. Both the shortness of the time and the absence of wasting forbids any such supposition; in fact, the shortening, together with the absence of wasting, are, in conjunction, quite irreconcilable with the theory of hip disease. There can be no doubt that the case is one of fracture of the neck of the femur.

Fracture of the neck of the femur in young children is an injury which has been grievously overlooked in the past; hence we must acknowledge our indebtedness for a most valuable paper recently published by Dr. Royal Whitman of New York. From this we gather that this accident is by no means of such rarity as I should have expected to learn, but that, on the contrary, it is an injury which occurs with sufficient frequency, for Dr. Whitman has himself seen no less than 10 cases in the course of 5 years. From a study of our two cases you will be easily able to conceive that in the absence of especial care in the use of the tape-measure such a fracture may very readily find its way into the category of cases of hip disease, and I have no doubt that this has been the usual fate of such injuries in young children. The mistake in diagnosis having once been made the further course of the case is easy to imagine; the child is put into a Thomas's splint, which no doubt will afford considerable relief, and after a few months of this treatment the limb will be found to have largely regained its utility and the surgeon will cherish the belief that the disease has become cured under his treatment. It is true that there will be some shortening and adduction of

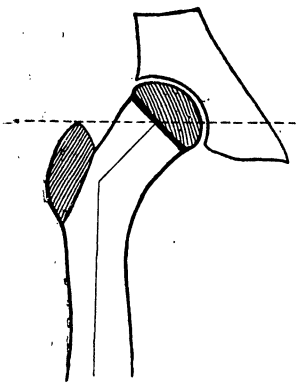
[1] Inter-colonial Medical Journal of Australasia, September, 1897.

[2] The explanation of this is very simple. The attachments of the muscles passing from the pelvis to the limb are approximated by the shortening. It is obvious that, given an equal bulk of the thigh muscles in the two limbs when one set of thigh muscles is shortened, such diminution in length must be attended by corresponding increase in circumference.

Digitized by Google

the limb, but on the whole there is ample ground for satisfaction at having got rid of the disease in so short a time and without abscess formation. We could regard an error of diagnosis with tolerance if the worst evil resulting from it could be shown to be merely an erroneous belief that we had treated a case of hip disease with great skill and success, but unfortunately this is by no means the case. If we refer to the account of the 10 cases narrated by Dr. Whitman we make the striking discovery that although the result may seem to be fairly good after only a few months have elapsed since the injury, yet the shortening steadily increases as the years pass by and goes on increasing. The explanation given by Dr. Whitman of the causes of this progressive shortening do not appear to me to be quite sufficient; he attributes it to the depression from yielding, due to too early use of the limb during the process of repair and to the later sinking of the neck due to the strain to which it is exposed by the deformity. That which, however, appears to me to be by far the most potent factor in the production of the increased shortening is the altered position of the upper fragment containing the growing epiphysis and the consequent elongation of this upper fragment in a faulty direction. When fracture of the femoral neck occurs, with the consequent drawing up of the trochanter, there is brought about a rotation of the head fragment upon an antero-posterior axis, so that the growing fragment, instead of inclining obliquely downwards, has its direction altered to one more directly outwards. The effect of this will be at once understood by a reference to Fig. 1 and Fig. 2. Fig. 1 depicts the neck obliquely and normally placed; in Fig. 2 the obliquity is represented for the sake of

FIG. 1.



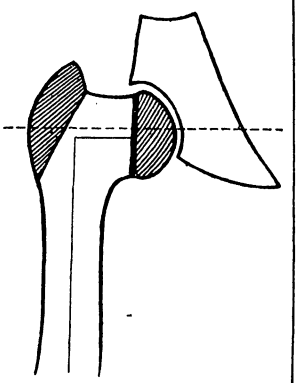


FIG. 2.

simplicity as completely abolished, so that the direction of the neck is horizontal. Now it is clearly by virtue of the obliquity of the neck that the upper epiphysis contributes to the production of the length of the limb throughout the whole period of growth; it is therefore equally evident that when the obliquity of the neck is abolished, as in Fig. 2, the contribution of the head epiphysis to the length of the limb ceases. The same considerations hold good for change in the direction of the neck of any degree intermediate between the normal direction and the complete effacement of obliquity portrayed in Fig. 2, and the impairment of the function of the head-epiphysis as a length-producing agent will be in exact proportion to the deflection upwards of the neck as a result of the injury. It is needless to say that while growth progresses normally in the other limb the injured member will lag behind its fellow, so that the shortening will be increasing and progressive throughout the entire period of growth. Looking again at Fig. 2 I would observe that although the production of length by the growth of the head-epiphysis is abolished once and for all by the deformity resulting from the fracture the epiphysis does not thereby become inactive; its growth proceeds, but the growth which should have been productive of increased length is now converted into an agency for the production of a wholly-evil increase in breadth. Now this increase in breadth through the lengthening of the misplaced neck serves only to increasingly accentuate the alteration of the angle formed by the neck with the shaft of the bone; and the rendering of this angle more acute means a commensurate degree of adduction of the limb, and adduction of the limb further implies a proportionate degree of apparent shortening, together with a slight though practically inconsiderable amount of real shortening. Thus we are confronted with two distinct and separate agencies at work to bring about progressive and increasing disability throughout the whole period of growth. First, the absolute loss of length owing to the abolition or diminution of length-production by the growth of the head epiphysis; and secondly, the added apparent shortening due to increasing adduction of the limb caused by lengthening of the neck in a horizontal direction; and this heaping of Pelion upon Ossa must inevitably make for disastrous lameness. It is hardly necessary for me to point out the enormous difference thus disclosed between fracture of the neck of the femur in a growing child and a similar injury in the adult. The latter is threatened by none of the progressive evils I have been depicting; and if the fracture happens to be an impacted one we gladly accept the result as it is with the slight amount of deformity present, for that deformity will be the end of it. In the case of a child, however, the importance of recognising the injury and treating it correctly is supreme. The first step towards recognising the nature of the injury is to be alert to the possibility of its presence in every case of even moderately severe injury to the hip in a child. A careful, even fastidious, use of the tape-measure can then hardly fail to lead us to a correct diagnosis.

The treatment is obvious; the indication is to open out the angle formed by the neck with the shaft. By doing this the obliquity of the neck will be restored and in proportion as this is effectively accomplished will the subsequent ills be diminished or annulled. The trochanter must be firmly fixed with one hand while the other abducts the thigh and an efficient retentive apparatus should fix the limb in this position. It is open to question whether the best time for doing this will be immediately after the accident. Personally, I should prefer to allow a period of three weeks to elapse for soft union to become established between the fragments in their faulty position, for I conceive that if undertaken in the first instance it might result in failure to draw the neck downwards, producing instead a most undesirable separation of the fractured surfaces and possibly non-union. Again, in an older case, where union is firm and the progressive shortening in full swing, it would appear that the evil could be largely remedied at any period, either by osteotomy of the femoral neck or of the shaft immediately below the trochanter, abduction of the limb being the object aimed at in either case. Of this, however, I am unable to speak with the confidence born of experience and it is of trivial moment compared with my primary object, which is to point out the importance of accurate diagnosis, the dreadful chain of ills which wait upon its default, and the principles which must guide us in our efforts to combat them.

THE MEATH HOME OF COMFORT.—This admirable institution provides for the care of epileptic women and girls. It has been in existence some five years and has already done good service. The report of the medical officer, Mr. P. Dundas Minchin, speaks most favourably of the improvement seen in the patients after their stay at the home. But of course all this work costs money and the committee is sorely hampered for want of funds. Although the home is situated in the country, near Godalming, yet there is great need in addition of a small house at the seaside. This would materially improve the health of the patients by means of enabling the committee to send them there for change of air and would also be a great boon to the nurses, whose work is necessarily trying, as a rest house. The hon. secretary is Mrs. L. H. Burrows, the Vicarage, Godalming.

THE PLAGUE IN INDIA.—We are extremely glad to learn from the Anglo-Indian papers received by the last mail that the plague has been rapidly declining of late at Bombay—where on June 24th for the first time since last year there had not been a single death from this disease reported in the city—Karachi and the Punjab districts. There were still a few cases returned at Calcutta. It still remains to be seen, however, whether this decline is to be attributed to the effect of seasonal changes alone or whether there will be any recrudescence of the epidemic on the approach of the cool weather.

SOUTH AFRICAN DRUGS IN THE TREATMENT OF DYSENTERY AND ULCERATION OF THE STOMACH AND INTESTINES.

BY JOHN MABERLY, M.R.C.S. ENG., L.R.C.P. LOND.

IN THE LANCET of Feb. 6th and 13th, 1897, I published an article entitled "Dysentery and its Treatment, with an Account of Six Years' Experience in the Transvaal and Matabeleland in the Use of Monsonia as the Curative Agent.' In that article I gave records of 100 cases of acute and chronic dysentery treated with Monsonia ovata and Monsonia Burkei resulting in only one death, and a good deal of interest was aroused, especially among Indian medical men, concerning the results obtained. As stated in the above-mentioned article, I was unfortunate in having all my supplies of the plants destroyed during the Matabele rising of 1896 and till now I have been unable to obtain a fresh supply of them. I have, however, at last succeeded, through the kind assistance of Professor MacOwan, the Cape Government Botanist, in obtaining a considerable quantity of the plants in question, so I now hope that the drugs will get a fair trial by my fellow practitioners, and that their value or otherwise will be thoroughly tested by competent observers in other parts of the world.

Since returning to Africa in June last year I have gained a good deal of information, largely through the help of the friend above named, regarding the history and botany of the order to which the plants belong, and I propose in this paper to give a short sketch of what is known up to the present regarding the plants and the uses to which they have been put in the past, as well as the records of one or two fresh cases which have come under my notice and which help to throw some additional light on their action. The natural order Geraniaceæ is very largely represented in South Africa, many species and even genera being peculiar to this country and quite unknown in any other part of the world. The whole genus Monsonia, to which the plants I have chiefly used belong, comes under this head, as also do a great many Pelargonia, including the sub-genera Hoarea, Seymouria, and Polyactium, possessing tuberous or fleshy roots. It is to various species of these plants that we find that peculiar medicinal properties have been ascribed and they seem to have been matters of common knowledge, judging by the records to be found among the writings of the earlier explorers of the country. In the well-known work entitled "Travels in Europe, Africa, and Asia between the years 1770 and 1779," the author, Charles Peter Thunberg, M.D., afterwards Professor of Botany in the University of Upsal, makes the following note respecting his visit to Cape Town in 1773: "Many gerania with their red and pulpous roots grow in the sandy plains near the town, and as these roots are of an astringent nature the country people used them in the diarrhœa and dysentery." The plants here referred to as gerania are some varieties of tuberous-rooted Pelargonia, probably Pelargonium triste, which grows about Table Mountain. The next written records traceable are to be found among the MS. notes of Dr. Mackrill, a medical man of repute at the Cape early in the present century. He had been deputed by Lord Charles Somerset in or about 1814 to travel through the then thinly-peopled district bounded by the Sneeuwberg and the still less known country adjacent to the Great Fish River for the purpose of selecting a site for a Government tobacco farm. During his travels he assiduously registered in his diary everything which came under his notice respecting native or Boer remedies. Among others he notes the use of Monsonia in the treatment of some forms of dysentery. In 1850 Ludw. Pappe, M.D., Colonial Botanist and Professor of Botany in the South African College, published a small work entitled: "Floræ Capensis Medicæ Prodromus, or an Enumeration of South African Plants used as Remedies." In his preface, after expressing regret at the total want of coöperation on the part of the country practitioners in making themselves acquainted with the various domestic remedies commonly used, he says: "There can, indeed, be no doubt amongst reasonable men that, judging from the vast extent of the South African territory and from the richness of its almost inexhaustible flora, many highly useful officinal drugs will still be discovered. However, the greater part of our information on this point we owe not so much to scientific research as to the experience of the colonial farmer residing in the more remote parts of the interior, to occasional travellers, or to the wandering native." In his work we find the following concerning Monsonia: "The Keita of the Hottentots.—The root and herb of this plant are very astringent and used with great success in dysentery." Regarding the Pelargonium triste there are the following remarks: "The scarlet-coloured root of this Pelargonium is somewhat astringent. If dried and pulverised it is useful in diarrhœa and certain forms of dysentery when purgatives have been previously given." Again, under the heading Pelargonium antidysentericum he writes: "This plant, which is indigenous in Namaqualand, has tuberous roots which often attain the size of a man's head, and are called *t'Namie* by the aborigines, who boil them with milk and make use of them in dysentery." He mentions various other Pelargonia as medicinal. Since Pappe's time, Mr. Andrew Smith, M.A., formerly of Lovedale Mission, where he was exceptionally well placed for obtaining the traditional medical lore of the Kafirs and Fingoes, published a work entitled, "A Contribution to the South African Materia Medica," which has run through three editions, the last is dated 1895 and contains a good deal of information gathered from various sources concerning medicinal plants in Africa. He mentions the Monsonia ovata and Monsonia biflora as being well known for their curative properties in dysentery. From these various statements we gather that the medicinal properties of various plants belonging to the order Geraniaceæ have been known to the inhabitants of South Africa for more than a century at least, and it would appear very extraordinary that plants which have been persistently employed for such a length of time should not contain some of the properties which have been ascribed to them. Among the laity diarrhœa and dysentery are terms which have been employed indiscriminately to denote two distinct classes, which, however, they look upon as the same in many instances. My own experience leads me to believe that the plants in question are quite useless in diarrhœa, at any rate in the form of spirit extracts, and are only useful in cases of dysentery or in some other forms of ulceration of the intestines and stomach.

When in England last year I had some specimens belonging to a tuberous rooted species of Pelargonium sent to me in mistake for my old plants the Monsonia ovata, and although at that time I knew nothing of the uses to which these plants had been put, except that I heard through a lay friend that they were very useful in dysentery, I made a tincture in the usual British Pharmacopœia manner from the dried pounded roots. Among other cases in which I used this tincture are the following: one of chronic dysentery and the other of gastric ulcer. For the records of the first case I am indebted to Surgeon-Lieutenant A. W. F. Russell, Indian Medical Service, who was himself also the patient.

CASE 1.—The patient went to India in October, 1894. In February, 1895, he had a slight attack of dysentery at Ferozepore in the Punjab, from which he soon recovered. In June he had a second attack during which he passed several sloughs and it resulted in his being invalided home in October, 1895. He returned to India apparently cured in September, 1896, but in October he had a third attack of dysentery which lasted about eight days, and on Feb. 14th, 1897, he had a fourth severe acute relapse of the disease, the history of which I will give in his own words: "This attack was caused by eating stale and indigestible food for some days and also precipitated by a slight chill. First felt pain in abdomen, then slight diarrhœa. This was on Feb. 14th, 1887. Feb. 15th: Worse during the night, a distinct rigor. Temperature 99·4° F. Feb. 16th: Thirty to forty motions, bright green matter mixed with a considerable quantity of blood. Feb. 17th: Condition worse, stools more frequent, consisting of mucus and blood. Feb. 18th: Worse. Forty to fifty stools *per diem*. All this time taking ipecacuanha and tinctura opii. Feb. 19th: Passed some large sloughs of mucous membrane. Feb. 20th to 22nd: Motions almost continuous, much straining, some sloughs. Feb. 23rd: Seen by a medical board and ordered to proceed to England at once. Started that night for Karachi, carried in dooly to railway station. Improvement at once on being moved, better in train, worse again on arriving at Karachi.

Digitized by Google

Remained at Karachi till March 4th; started for Bombay, arriving there on the 6th and leaving the same day for London by the P. & O. s.s. *Caledonia*. During the voyage was only once able to come up on deck, motions varying between five and eight per diem, mostly mucus and blood. Arrived in London March 25th. March 26th: Motions seven in number, more blood and mucus. Received a bottle of Dr. Maberly's tincture (supposed to be made from the root of one of the Pelargonia); took three two-drachm doses per diem for three days, then noticed that blood had entirely disappeared from the motions, which, however, remained frequent—five per diem. In two more days mucus disappeared from the stools, which had been somewhat like frog-spawn mixed with fæces. Stools remained too frequent. Then took 1 gr. of opium in the morning. This reduced the stools to one or two *per diem* and gave formed motions with no pain. May 5th, 1897: Have not taken the medicine for a fortnight and the stools remain healthy—one *per diem*—no mucus or blood, but there is a tendency to diarrhœa, especially on cold days. This is easily checked, however, and I have almost recovered my former strength and feel fit for work. I am convinced that the tincture kindly supplied by Dr. Maberly exerted a decided influence in healing the ulcers, which must have existed in numbers in the large intestine."

CASE 2.—This case was one of ulceration of the stomach of some months' standing. The following is the history:—Capetown, Dec. 6th, 1897. The patient was a man, aged thirty-two years, fairly well nourished but weak and sallow-looking. His pulse was 82, feeble and small, and he had suffered for the last twelve months from cramps and pain in the epigastrium at irregular intervals, sometimes daily and continuous, at other times coming on about an hour or more after meals, especially worse after eating meat. The pain sometimes became excruciating and appeared to pass round to the back and was then usually followed by vomiting. The vomited matter was generally partially digested food mixed with a dark-coloured fluid and contained a sediment which the patient said was well described as similar in appearance to coffee-grounds. The bowels were irregular. The motions consisted generally of a small quantity of loose fæcal matter mixed with slime, and passed three or four times a day. They were never what the patient called satisfactory. He was usually seized with an irresistible impulse to stool three or four times a day. His appetite was poor. The patient stated that the first attack occurred in November, 1896, when in Bechuanaland, with pain in the stomach, which gradually became worse and lasted continuously for about five days. The bowels were confined and he vomited bilious matter during this time. On palpating the abdomen a localised tender spot was discovered in the left side of the epigastric region, the stomach was not dilated and otherwise the abdomen and chest were normal. Half an ounce of tincture of pelargonium was given at once and powders of 10 gr. each of the powdered root were administered three times a day for the next three days. The patient was seen again on Dec. 9th and he then stated that he had felt quite well since the first dose of tincture except for an hour or so on the 8th, when he felt some dull pain on the right side of the abdomen. On examination the tender spot in the epigastric region had disappeared; the large intestine appeared to be loaded with fæces, however. 4 gr. of calomel to be followed by 1 oz. of compound mixture of senna were ordered. On Dec. 10th the patient passed a very large motion after taking the draught and said he felt better than he had done for months previously. He was given one more dose of 2 dr. of tincture of pelargonium and had no further medicine. He has been in excellent health for more than four months and is apparently completely cured.

Regarding this case I own I was rather sceptical about the patient's statements as to the results of the drug and was inclined to doubt whether he had not been suffering from a delusion, but I found on inquiries from his employers and the medical man who had treated him previously that he was a trustworthy, hard-working man and that what he told me was evidently quite correct. I have, therefore, risked publishing, although up to the present I have not had any corroborating cases and I hope that it may induce some other members of the profession to give the drug a trial in some typical cases of gastric ulcer and to either communicate their results to THE LANCET or else to myself, so that we may be able to come to a definite opinion on the subject.

It is a great pity that I have not been able up to the present to name the exact species of Pelargonium to which these roots belong, but I do not anticipate any special difficulty in doing so in case the value of the drug is established. It is very similar to the Pelargonium reniforme but, according to Professor MacOwan, is not that plant. Only those who, like myself, have taken an interest in ferreting out the plants used as medicine by some of the colonists, know how tiresome it is to get them to send a flowering specimen of the plants used. Their great idea appears to be to keep the knowledge of any valuable remedy to themselves in the hope of obtaining a large recompense for divulging what they think is a secret. I have specimens of the leaves and a large quantity of the roots, and as they are very distinctive there will be no difficulty in tracing them other than the time and expense of a journey to the districts in which they grow. There are several varieties of similar plants, of one of which—the Pelargorium triste—I have collected a considerable quantity. This one contains a body apparently exactly similar chemically to that of the Pelargonium in question, and probably its action would be similar physiologically, but at present I have not had an opportunity of putting it to the test, although it has been used in the treatment of "diarrhœa and dysentery" successfully according to lay records. I have tried the tincture made from the Pelargonium in another case of chronic tropical dysentery in the Somerset Hospital, Capetown, under the charge of Dr. Elliott, but the result was doubtful although the drug was combined with opium. The patient, however, appeared to improve whilst taking the drug, but I only had a small quantity of it at the time and the treatment was not continued long. However, I think it is pretty certain that these tuberous-rooted Pelargonia will not be found so effectual in the treatment of dysentery as the Monsoniæ, although, judging by Case 1 given above, they also have the same action on ulceration. But for some reason they do not appear to me so certain in their action. They will, however, be very valuable if it is found that they have a specific action on ulceration of the stomach. For diarrhœa they have proved themselves in my hands quite useless. In this respect they are similar to the Monsoniæ. With regard to the latter drug I may state that I gave it lately in large doses (½ oz.) in a case of acute diarrhœa with mucus and blood in the stools which, however, was not, I think, pure dysentery, the peculiar tenesmus of that disease being wanting. The drug had no effect whatever. This form of enteritis is not uncommon here; it yields at once to a powder of the compound powder of jalap, the compound powder of ipecacuanha, and phenacetin, and has no tendency to recur. It is probably not due to the same poison as tropical dysentery.

These facts tend to show what I believe will eventually be proved—namely, that the real value of the tuberous-rooted Pelargonia as well as that of Monsonia ovata and Monsonia Burkei lies in their action on ulceration of the stomach and intestines, including that due to acute and chronic dysentery. If this is so we shall probably find that they also have an effect on the typhoid ulcer. This, I believe, is the case any time after about the eighteenth day of the disease. I have given the tinctura monsoniæ in three cases of this disease; twice towards the end of the third week and once in a very bad relapse in the fifth week, with blood in the stools. The first two cases were well by the twenty-first day. In the third case the patient slowly recovered; the hæmorrhage and diarrhœa ceased very soon after the second and last dose of 2 dr. The drug in the first cases appeared to induce constipation, which was, however, easily overcome by a large dose of olive oil. Dr. Foxwell of Birmingham used the tinctura pelargonii in a case of chronic diarrhœa with granular kidneys without any very distinct benefit and also without any ill-effects, which is perhaps worth recording as showing that the drug has no poisonous effect on diseased kidneys, the patient being, as he states, peculiarly susceptible to drugs. In fact, judging by the excessive doses given by the colonists, usually about a wineglassful of strong tincture made with brandy, it is almost certain that the plants contain no poisonous qualities even in quantity.

With the kind assistance of Mr. A. M. Cheyne, analytical chemist to Messrs. Burgoyne, Burbidges, and Co., an attempt was made to discover the active principle of the root of the Pelargonium used in the two cases recorded in this article. The quantity at our disposal was too small for a thorough analysis. We were, however, able to satisfy ourselves that

Digitized by Google

there was at any rate, no alkaloid present. The chief body found was a reddish amorphous powder, representing about 6 per cent. of the whole dried roots, this was soluble in rectified spirit and it gave the reactions typical of the class of vegetable bodies named tannins, being allied to that which occurs in cinchona, catechu, salix, &c. It is probable that the action of the drug depends on this substance. There was besides this another body somewhat similar, soluble in hot water, which was not precipitated by gelatin but otherwise gave reactions characteristic of the tannin group. A third body, soluble in ether and in rectified spirit at a temperature of 90° F. but insoluble or only slightly so in cold spirit, apparently a fatty acid, was also separated.

It has been my endeavour in writing these articles to place as much as possible any special knowledge gained at the disposal of my fellow practitioners, in the hope that some among them will be able to carry on the work of further proving or disproving the value of the drugs, which in my own hands have certainly yielded remarkable results. It is almost impossible for a private practitioner to complete single-handed the work necessary to prove absolutely the value or otherwise of a new series of drugs. He has to wait for opportunities for the trial of remedies in suitable cases; the mere necessities of existence compel him to be more or less a fixture wherever his lot may place him, few having the means at their disposal to shift quarters as required to parts where this disease or that is prevalent in order to test the value of some reputed remedy. On this account, therefore, I do not apologise for placing before my fellow practitioners what I am conscious is an incomplete investigation. There are several drugs in South Africa which are well worth the trouble of investigating—some, indeed, which, like the plants referred to here, promise to fill gaps at present existing in the Pharmacopœia. But the work of tracing the plants themselves and then proving their qualities is too prodigal of time and means to be undertaken by private practitioners, and unless some organised effort is made to rescue them from the oblivion in which they are at present sunk and to put them to the test of scientific experiment their virtues will remain unknown to the great bulk of the suffering humanity for whose benefit they were intended. In order that the medical profession may be able to obtain reliable preparations of the plants I have sent a good quantity of Monsonia ovata and Monsonia Burkei (or biflora) as well as some of the Pelargonium of uncertain species, also the Pelargonium triste to Messrs. Burgoyne, Burbidges, and Co., of 16, Coleman-street, London, E.C., who will make tinctures of the various sorts. I have been induced to do this in the first place because I know myself how extremely difficult it is to get reliable plants collected; and, secondly, by the fact that a certain firm in Port Elizabeth took the liberty about June last year of using extracts of my last article in THE LANCET without my knowledge as a means of advertising a certain preparation which they sold as "Tinctura monsoniæ." Seeing that the said papers could not have come to their knowledge till about the end of March and that in ordinary seasons the Monsonia ovata and Monsonia Burkei are at that time of the year either dead or in a withering condition it appears probable that the said preparation could not possibly have contained any active properties even if made from the species mentioned. There are several other species of Monsoniæ without any medicinal properties. Any experiments with the drug carried on under such circumstances would be most disappointing and very damaging to the reputation of a new drug and, perhaps, to that of the unfortunate medical man who had interested himself in bringing it before the profession. As a scientific worker I am quite prepared to find that other medical men may not have the same success as I have myself obtained with the plants in question; the only stipulation I would make is that their experiments shall be with preparations which I feel sure are what they claim to be. In this way only shall we be able to come to any definite conclusion.

For the benefit of those who may feel inclined to give the drugs a trial I may state that my experience leads me to believe (1) that they contain no poisonous properties; (2) that the Pelargonia are more suitable for ulceration of the stomach and upper portion of the intestinal tract and the Monsoniæ for that of the lower portion; and (3) that doses of two drachms are about the minimum for adults except perhaps in the case of typhoid fever, in which disease drachm doses of tinctura monsoniæ after or about the eighteenth day of the disease are sufficient, two or three such doses being all that is necessary, combined with or followed by some laxative, such as an ounce or so of olive oil. As to the Pelargonia in this disease I have had no experience.

In conclusion, I may add that in placing these observations before the medical profession I do so with a certain amount of diffidence and shall await their verdict on the drugs in question not without some anxiety, as no one is more conscious than myself of the uncertain action of drugs in the experience of different men in different parts of the world, and we all know how drugs in which some men have asserted their implicit faith have in the hands of others proved more or less disappointing. It is, however, only after a somewhat extended experience that I have formed any opinion on the plants in question, and I can only hope that they will prove themselves worthy of the faith I have placed in them in thus introducing them to my fellow practitioners.

Capetown.

HÆMATURIA AS A SYMPTOM: METHODS EMPLOYED IN MAKING A DIFFERENTIAL DIAGNOSIS;

WITH 19 CASES ILLUSTRATING POINTS OF INTEREST IN THE DIAGNOSIS OF RENAL AFFECTIONS CHARACTERISED BY THE PRESENCE OF BLOOD IN THE URINE.

BY DAVID NEWMAN, M.D. GLASG.,
SURGEON TO THE ROYAL INFIRMARY, GLASGOW.

(Concluded from p. 80.)

2.—Passive Hyperæmia.

(*a*) *Pressure on the renal veins.*—There are many lesions which may lead, by pressure upon the renal veins, to a passive hyperæmia, which reveals itself during life by the presence of albumin or of blood in the urine. I have seen instances where large abdominal tumours or aneurysms have caused obstruction to the exit of blood from the kidneys and so produced a hæmaturia. Sometimes a similar condition is brought about by pressure of a greatly-enlarged liver, by syphilitic new formations, or by malignant tumours in the neighbourhood of the spine. Such conditions require only to be mentioned here, as they seldom come under the treatment of the surgeon.

(*b*) *Torsion of the renal veins.*—I brought before the Clinical Society of London[1] two cases of moveable kidney in which hæmaturia was a prominent symptom as a consequence of interference with the venous flow from torsion of the renal veins. When the kidney was displaced in certain positions blood appeared in the urine and when the displacement was rectified by operation the symptoms disappeared and the hæmaturia ceased.

CASE 11. *Moveable kidney caused by a fall; symptoms—severe paroxysmal renal pain, sickness, and vomiting; history of hæmaturia, &c., simulating renal calculus; hæmaturia from hyperæmia; torsion of the renal vein.*—In this case the displacement of the kidney was caused by direct violence. Coincident with the accident the patient suffered pain in the renal region and at the same time he noticed a quantity of blood in the urine. The hæmaturia continued for several days and then gradually disappeared. Following the accident the pain in the lumbar region was so severe that he had to avoid work for over three weeks and after that time he required to be very careful not to over-exert himself, otherwise both the pain and the hæmaturia returned. This condition continued during four years. When he was at rest he had little or no discomfort, but severe suffering was readily brought on by any sudden movement of the body. Complete rest afforded marked relief to his suffering and if he avoided exercise of any kind the pain and hæmaturia seldom troubled him. The urine when free from blood was strictly normal, but when the hæmaturia came on the blood was intimately mixed with the urine, and the quantity of albumin present was in proportion to the hæmoglobin. No coagula, tube-casts, or histological elements of significance were found in the urine at any time. There was no

[1] Transactions of the Clinical Society of London, vol. xxx., p. 65.

Digitized by Google

suppression of urine, but during the attacks the urine was concentrated and when they passed off it was dilute and copious.

CASE 12. *Severe paroxysmal renal pain and hæmaturia; occasional blood-casts in the urine; moveable displaced kidney; torsion of the renal veins.*—In this case the patient suffered from severe paroxysmal renal pain and hæmaturia. These paroxysms of pain usually came on after exercise and lasted for several minutes at a time, while during the six months prior to admission he was almost constantly suffering from an aching pain in the left side. At the onset of the attacks of paroxysmal pain the urine was of a dark red colour and contained a large quantity of blood, but gradually the amount of blood diminished and the urine became of a brighter red. When the patient was kept strictly to bed he had no paroxysmal attacks and no hæmaturia or albuminuria. The presence of blood-casts in the urine was observed after the patient had been under observation for a considerable time. At first the case was considered to be one of renal calculus, but the presence of blood-casts in the urine suggested the source of hæmorrhage to be the renal tubules rather than the pelvis of the kidney. In this case the symptoms—namely, paroxysmal renal pain increased by exercise and relieved by rest, hæmaturia, and tenderness on palpation over the right renal region—all pointed to a calculus in the kidney; but the occasional presence of a few tube-casts and traces of albumin, without pus or blood, indicated that the morbid condition affected the tissue of the kidney, while the occasional appearance of blood-casts of the uriniferous tubules pointed to the origin of the hæmorrhage as being a marked but at the same time transitory passive hyperæmia from venous obstruction. At the operation a rotation of the kidney was found, the lower margin presented forward causing the ureters and blood-vessels to be coiled round one another, and so impeded the circulation of blood. As a consequence more or less passive hyperæmia was produced which varied in degree according to the precise position occupied by the kidney at the time. (See also Case 1.)

It is manifest that in such displacements of the kidney as those described the surgeon has to deal with a passive hyperæmia of the kidney due to local causes. In some instances the obstruction may be entirely venous, in others the arterial circulation may also be interfered with. When the efferent resistance is increased the veins and the venous radicals surrounding the uriniferous tubules will become distended. This increased resistance to the flow of blood from the kidney will lead to very considerable augmentation of the blood-pressure within the glomeruli. It is easy, therefore, to understand why blood-casts, blood corpuscles, and albumin appeared in the urine.

(c) Reflex spasm of the arterioles.—Examples of reflex inhibition of the functions of the kidney are numerous. For instance, complete suppression may follow the passage of a catheter and may be succeeded by a hæmaturia lasting for some days; then cases are seen of unilateral obstruction such as is produced by the presence of a calculus in one ureter causing complete anuria which may be more or less prolonged. Again, in cases of transitory hydronephrosis, when the obstruction on one side reaches a certain point the kidney on the opposite side may fail to act, even although the hydronephrosis continues to increase in size. In the *Glasgow Medical Journal* for March, 1896, p. 211, I reported a case of suppression of urine due to reflex spasm followed by the passage of urine containing blood. The case was one of intestinal obstruction. The patient complained of considerable pain in the region of the bladder and inability to urinate. No distension of the bladder could, however, be detected and on passing a catheter no urine escaped, although the instrument was clearly within the cavity of the viscus. Dry-cupping was applied over both kidneys and soon afterwards the patient passed 8 oz. of urine, which contained blood and a quantity of albumin larger than the blood accounted for; also some pus, but no tube-casts. A similar case to this I have recorded in the Transactions of the Clinical Society of London, vol. xxx., p. 78, Case 6. (See Case 14.)

The existence of a marked hyperæmia of the kidneys in cases of acute abdominal affections is not simply a coincidence—I should be almost disposed to regard it as a frequent occurrence and one which should be carefully looked for, and when indicated by prolonged suppression of urine the question of the relief of tension should be carefully considered. When the anuria is followed by the excretion of albuminous and bloody urine it indicates that there has been a serious disturbance to the circulation. The spasm is probably due to morbid motor impulses conveyed from the nerves proceeding from the solar plexus. Sudden relief of intra-abdominal pressure, as, for example, the removal of a large abdominal tumour or the evacuation of ascites fluid, may be followed by either an albuminuria or a hæmaturia, which seldom lasts, however, more than a few days.

3.—Inflammatory Hyperæmia.

(a) Nephritis, acute and chronic.—In cases of acute nephritis, especially when the inflammation of the kidney is a sequela of typhoid fever, scarlet fever, pneumonia, or erysipelas, a considerable quantity of blood, and even blood-clots, may be found in the urine, which may be dirty rose-colour, dark-brown, or almost black. When the urine is very dark in colour it has been observed that the proportion between the colouring matter and the red blood corpuscles has been lost—that is to say, that the colouration of the urine is not fully accounted for by the corpuscles present. This anomaly is probably accounted for by the circumstance that the vessels of the kidney are under great inflammatory tension and probably the inflammatory process is associated with rapid disintegration of the red blood corpuscles and solution of the hæmoglobin. This explanation is supported by the fact that when such urines are examined frequently at different times of the day a true hæmaturia may be at one time discovered, at another a true hæmoglobinuria, while on a third occasion the conditions may be mixed.

Hæmaturia is not only observed during the acute stages of nephritis, but when the disease is chronic occasional outbursts of blood may be emitted during a period measured by hours or even days. These sudden appearances of blood are known in many instances to be traced to some exciting cause. For instance, in some cases of nephropathic anæmia it is only necessary to apply a simple vesicatory to cause the appearance of blood, in other cases cold is the determining cause, or a slight strain or fall on the buttock, or, again, in others the hæmaturia may be provoked by an intercurrent malady. Hence in all cases of hæmaturia arising in anæmic persons from slight causes the question of Bright's disease should be considered.

Time was when a disease such as acute tubular nephritis would be clearly placed under the care of the physician only, and the idea of seeking the aid of the surgeon under any circumstances would not for a moment have been thought of. The theoretical barrier which at one time clearly demarcated the line between medicine and surgery has been moved and the limits of the surgeon have advanced, so that at present it is difficult to say what belongs to the physician and what to the surgeon. The new horizon of surgical activity is far-reaching, and not infrequently new fields of action have been discovered as it were by accident. Take, for instance, the occasional successful treatment of tuberculous peritonitis by abdominal section, which has followed, what cannot but be regarded in the first instance as "random operations"; again, in cerebral surgery the gravest symptoms have in some instances disappeared after trephining, even although no special diseased condition has been discovered; so, also, in renal cases improvement has taken place after free incision of the kidney without any lesion being disclosed sufficient to account for the symptoms. To explain cases such as those referred to considerable speculation has been brought to bear on the subject and various theories have been offered to account for the benefit derived by the patient, but it is only through time and by larger experience that anything like a reliable opinion can be formed. It seems to me that in some of those cases the relief of internal tension may account for the benefit procured; the relief of tension within the peritoneal cavity, within the cranium, and within the firm fibrous capsule of the kidney may possibly explain the good effects of incision in a few instances, but not in all.

The attention of the profession was directed to the subject of "Albuminuria associated with Kidney Tension" in an article in THE LANCET of Jan. 4th, 1897, by Mr. Reginald Harrison. In his first contribution he makes the following observation: "Since the introduction and the more general adoption of direct exploration of the kidney through an incision from the loin or otherwise a certain proportion of cases have been met with where it failed to reveal any obvious cause for the symptom or symptoms which led to the adoption of the proceeding. It has, however, been frequently

Digitized by Google

noticed that such cases are often completely and permanently cured by what was done." He then cites three cases in illustration—the first an instance of post-scarlatinal nephritis; the second a nephritis from exposure to cold and damp; and the third case one of subacute nephritis following influenza; and in all of these he believed that considerable benefit was derived from the relief of renal tension by incision of the kidney. The details of the cases are not sufficiently complete for the reader to form an independent opinion from the facts stated, but from what I have seen of other cases I am willing to admit the justness of Mr. Harrison's conclusions as applied to the effects of increased vascular tension on the kidneys and their excretions. In corroboration of Mr. Harrison's view that inflammatory hyperæmia may lead to considerable pain in the kidney accompanied by albuminuria and relieved by incision the following cases may be quoted.

CASE 13. *Sudden suppression of urine, renal colic; hæmaturia; albuminuria; incision of the kidney followed by relief of pain and disappearance of albuminuria.*—In 1888, at the Western Infirmary, Glasgow, I saw a man who complained of severe pain in the loins, more severe, however, on the right side. It came on suddenly about two months previously and at the onset was accompanied by rigors and a sudden diminution in the quantity of urine. I ascertained from his medical attendant, the late Dr. John Moyes of Largs, that the urine at the beginning of the attack contained albumin, but no tube-casts were discovered. The specific gravity was from 1025 to 1030, but the daily quantity of urea was diminished. From 25 to 35 oz. of urine were passed in twenty-four hours. The patient did not complain of headache, nausea, or vomiting, and no other of the characteristic clinical features of nephritis was present, such as anasarca, effusion into serous cavities, anæmia or uræmic symptoms. When seen at the infirmary the urine contained a moderate quantity of albumin but no tube-casts and comparatively little deposit was thrown down on standing. There was a history of the passage of small oxalate of lime calculi and of occasional hæmaturia. While under observation he had several attacks of distinct renal colic, which led me to the conclusion that he was suffering from renal calculus, and he was advised to have an operation performed in the hospital. This he refused, but consented after some delay to have it done in private. On exposing the right kidney by a free incision in the loin the organ was seen to be enlarged, of a dark chocolate colour, and very tense. On examining the kidney with needles for the detection of a stone free bleeding occurred, and as no calculus could be discovered with the needles a free incision was made into the pelvis in order to explore with the finger. The bleeding was very free and the wound in the cortex had to be plugged with iodoform gauze. No calculus was found. I felt that I had made either an error in diagnosis or that my search had been imperfect and left the case with the belief that harm rather than good had been done by the operation, but to the satisfaction of the patient and myself he ceased to suffer any pain, the albuminuria disappeared entirely, and afterwards the patient enjoyed excellent health.

In this case, from the onset of the trouble till the time of the operation, albumin was constantly present and the quantity of urine remained considerably below the normal, but after incision the albumin disappeared and remained absent and the quantity of the urine increased. I have no doubt that in this case the relief of tension by the incision facilitated the renal circulation. Wet- or dry-cupping over the kidney may act in a somewhat similar way.

CASE 14. *Sudden suppression of urine; the pain at first diffuse, afterwards limited to the renal region; albuminuria; blood-casts; wet-cupping, with relief of urinary symptoms; inguinal hernia; operation; cure.*[2]—On May 20th, 1893, a patient, aged sixty-two years, came under observation on account of severe abdominal pain associated with sudden and almost complete suppression of urine, nausea, and vomiting; the pain at first was not limited to any particular spot, but was complained of all over the abdomen. When seen by me the pain had considerably diminished from what it was at the onset the previous day and physical examination of the abdomen did not cause much increase in suffering unless when firm pressure was made over the renal regions. The bowels had been moved freely and there was neither distension nor collapse of the abdomen; no hernia could be discovered. Only highly albuminous urine had been passed since the onset of the pain. The patient had an old stricture but the bladder was almost empty. The following table shows the state of the urine:—

TABLE I.—*Showing the Condition of the Urine before and after Suppression.*

Date.	Quantity.	Specific gravity.	Reaction.	Remarks.
1893.				
May 20th, 10 A.M.	20 oz.	1016	Acid	Slight trace of albumin. No blood. Pain set in at 11.30 A.M. and steadily increased till midnight.
May 20th, 11 P.M.	3 oz.	1018	Acid	Very albuminous. Blood drawn off by catheter.
May 21st, 8 A.M.	1 oz.	?	—	Highly albuminous. Blood-casts.
May 21st, 10 P.M.	4 oz.	1025	Acid	Ditto.
May 22nd, 10 A.M.	3 oz.	1028	Acid	Ditto.
May 22nd, 7 P.M.	—	—	—	14 oz. blood drawn off.
May 22nd, 11 P.M.	6½ oz.	1020	Acid	Highly albuminous blood-casts.
May 23rd, 2 A.M.	7 oz.	1018	Acid	Ditto.
May 23rd, 6 A.M.	10 oz.	1018	Acid	Less albumin and less tube-casts.
May 23rd, 11.30 A.M.	12 oz.	1016	Acid	Albumin and blood much less.
May 23rd, 6 P.M.	12 oz.	1016	Acid	Ditto.

The temperature was never above 100·3° F., the pulse averaged 88 and was of good strength, and the respirations were 22. There were numerous blood-casts in the urine. The skin was moist. From the presence of blood-casts it was evident that the source of the albumin was in the kidneys and the suspicion was aroused as to the possibility of there being an acute tubular nephritis. Acute febrile diseases and their sequelæ were excluded and there was no reason to suspect cardiac, pulmonary, or cerebral causes of albuminuria. I applied wet-cupping to the loin over both kidneys and removed in all 14 oz. of blood at 7 P.M.; by 11 P.M. the patient had passed 6½ oz. of albuminous urine and during the same night 17 oz. of less albuminous urine were excreted and the pain in the loins subsided. The patient remained moderately well for a day (the 23rd) when the pain in the abdomen recurred, but this time it was more marked at the umbilicus and on the right side just over the middle of Poupart's ligament, where there was some increased resistance and dulness on percussion. This pain rapidly became more severe and the patient presented the appearance of a case of acute intestinal obstruction. A very careful examination was made of the abdomen, when the only abnormality to be detected was the dulness and increased resistance just referred to at the region of the right internal abdominal ring. Suspecting a small strangulated inguinal omental hernia I operated and thus gave relief. The patient made a good recovery and the albuminuria disappeared in three days.

Mr. Harrison's cases were clearly instances of acute parenchymatous nephritis and they raise the question how far in such maladies incision into the kidney may produce beneficial results. Parenchymatous nephritis is a disease characterised by scanty urine of high specific gravity which is very albuminous and contains blood and on standing deposits blood-casts and casts of the uriniferous tubules which may be hyaline, epithelial, or granular, and associated with these renal symptoms other conditions are generally present, such as serous effusion, as shown by hydrothorax, ascites, and œdema, while at the same time symptoms of so-called uræmic poisoning may develop. Post mortem the kidney is found to be enlarged and softened and the uriniferous tubules show very marked changes, such as swelling of the epithelium with a marked tendency to desquamation, so much so that the tubules may become blocked. At the same time fatty degeneration of the epithelial cells is present and blood is very commonly

[2] Transactions of the Clinical Society of London, vol. xxx., p. 78, Case 6.

Digitized by Google

present in the tubules. The blood probably escapes both from the mucous surface of the uriniferous tubules and from the glomeruli. During life, as I have observed, the extreme tension of the kidney is very marked. Considering that the expansion of the kidney is limited by a firm, fibrous capsule any marked increase of tension in the parenchyma of the organ must seriously interfere with the circulation of the blood and so impair the nutrition of the component elements of the organ and interfere with its function. This raises the question, when an acute parenchymatous nephritis leads to suppression of urine and impending death of the patient, Is not the surgeon justified in stepping in and, by incision of the engorged organ, relieving the tension, which is probably impairing the circulation of blood and the performance of function? Because the kidney is an internal organ, and therefore not so easily reached as external parts, should it be treated otherwise than more superficial parts when presenting practically the same conditions?

In chronic tubular and parenchymatous nephritis occasionally the urine is coloured of a rose-tint or even darker red, but in the intervals between the hæmaturiæ the urine shows evidence of renal disease by the presence of granular or hyaline tube-casts and small quantities of albumin, while the fluid itself is of a low specific gravity. The appearance of blood in chronic Bright's disease is well recognised, and a careful observer is not likely to overlook this form of hæmaturia or mistake it for any other, unless the renal disease happens to be complicated by the presence of other lesions. I met with a case four years ago where considerable difficulty was experienced in the early observations. The case was introduced as one of hæmaturia, which certainly had been more profuse than is usually seen in cases of chronic Bright's disease and was associated with painful and frequent micturition, so much so that the question of tumour of the bladder or vesical calculus was raised, but on cystoscopic examination the bladder was found to be typically healthy. The patient was kept at rest in bed and on milk diet, and within a few weeks the blood disappeared from the urine. The urine all along, however, contained traces of albumin, its specific gravity was seldom higher than 1008, and on standing a precipitate containing finely granular and hyaline tube-casts was detected by the microscope. Such cases require to be recognised by the surgeon but do not strictly come within his domain.

(b) Tuberculous disease of the kidney.—In this malady the urine presents very marked variations at the different stages of the malady. In the initial phases of the affection the presence of the virus induces a congested condition of the organ and hæmorrhages occur which are analogous to the hæmoptyses in the initial stages of pulmonary tuberculosis (see Cases 15 and 16). When the kidney parenchyma and the calyces become more seriously involved the characteristics of the urine are more distinct, but this is not always the case. The physical characters of the urine are in some instances such that one can with certainty state that the urinary tract is the seat of a tuberculous lesion, while in other cases the excretion may be to no appreciable extent altered from the normal. Before destructive processes commence within the renal pelvis or substance traces of albumin and small quantities of blood may be detected, but when the tuberculous deposit has commenced to break down and evacuate into the ureter the quantity of albumin is increased, the urine is liable after a time to become alkaline, and along with greater or less quantities of debris of renal tissue pus appears in considerable quantity.

The albuminuria differs from that of Bright's disease in that the urine is not clear but contains much mucus, is viscid, cloudy and opaque, and does not contain tube-casts. The deposit contains small caseous masses mixed with renal débris and on standing, although a considerable amount of pus may be precipitated, a certain quantity remains suspended and imparts a cloudy appearance to the fluid.

It is only in rare instances that profuse hæmaturia occurs in renal tuberculosis. Trautenroth[3] records the case of a woman, aged twenty-four years, who was the subject of pulmonary tuberculosis in its early stage, but who also suffered from profuse hæmorrhage from a tuberculous kidney which necessitated nephrectomy. The pelvis of the kidney was filled with coagulated blood and upon one of the papilli a considerable ulcer was discovered. The parenchyma of the kidney was the seat of a diffuse tuberculosis. The urine before the operation was found to contain tubercle bacilli; the patient made a good recovery. Routier[4] records a somewhat similar case where the right kidney was the seat of a large tuberculous ulceration. Severe hæmorrhage occurred and continued during seventeen days, associated with renal colic; on making pressure over the right kidney blood was seen to escape from the right ureter by the cystoscope. The kidney was removed and the patient made a good recovery.

As the disease advances the odour of the urine as a rule becomes more and more offensive; the fluid deposits large quantities of mucus and triple phosphates, and on examination is found to be highly albuminous. Occasionally while the urine is pale and of low specific gravity there may be evidences of retention on the diseased side, as shown by increase in the renal swelling, with perhaps indistinct fluctuation and pain accompanied by general constitutional disturbance, or there may be complete suppression, death being ushered in by uræmic symptoms.

In addition to the diagnostic points already indicated the detection of the tubercle bacillus in the urinary débris is of great value. The method which I have employed most successfully is as follows. Allow a quantity of urine to stand in a conical glass in a cold place, for not more than six hours and from the deposit select a small quantity of débris; place it in a glass of ¾ per cent. salt solution. Having placed a small fragment of the débris on a clean cover-glass it should be spread out into a thin layer by pressing another cover-glass against it between the finger and thumb. On separating the cover-glasses a thin film of débris will be found adhering to each. The glasses must be air-dried and then the films may be more firmly fixed by drying over a spirit lamp or in front of the fire. The cover-glasses are then placed in or, still better, floated upon (with film side downwards) a solution of anilin magenta or a staining fluid of gentian-violet. When the film has become sufficiently stained the colour may be abstracted from all structures other than the tubercle bacilli by passing the cover-glass through a 25 per cent. solution of nitric acid. The action of the acid may be arrested by carefully washing the specimen in pure water. When examining the urinary débris for tubercle bacilli it is necessary in most cases to prepare at least half a dozen specimens. Should bacilli be present they will be recognised by a magnifying power of 750 diameters as minute rod-shaped bodies, coloured according to the nature of the staining fluid employed. They are from three to seven micro-millimetres long, may be straight, but are more frequently curved or bent upon themselves at an obtuse angle, are frequently beaded, and occur in bundles or singly. From the urine the micro-organisms are not easily cultivated, as putrefactive bacteria contaminate the culture and destroy the specific bacilli. Koch, however, states that he has succeeded in cultivating tubercle bacilli from cases of tuberculous pyelitis.

In some instances the bacilli in the urine are so few in number that it is difficult or almost impossible to discover them simply by the microscope; in such instances inoculation experiments may help to clear up the diagnosis. When tuberculous urine is injected subcutaneously or into the peritoneal cavity of rabbits it produces a typical tuberculosis, while normal urine when aseptic becomes absorbed without producing any evil effect, or when septic may produce a suppurative peritonitis. If, however, the experiment is performed with care healthy urine produces a negative result, but if the urine contains tubercle bacilli or their spores acute miliary tuberculosis is developed in the course of a few weeks when the injection is made into the peritoneum, or if the urine is placed underneath the skin a hard tuberculous nodule is formed.

Besides the detection of the tubercle bacillus it is necessary to determine whether the disease is on one or both sides. I have several times had occasion to examine by ureteral catheterisation cases of tuberculous pyelitis in which it was considered of importance to determine the extent to which the disease had involved one or both kidneys. Catheterisation can only determine the organ to which the tuberculous disease is limited, it cannot indicate the extent of the tuberculous lesion in the affected organ, but to make sure that one kidney was free from disease was at the time I first employed catheterisation considered to be a point of importance. The first time I succeeded in doing this was in 1886, when I

[3] Centralblatt für Chirurgie, 1896, No. 16.

[4] Bulletin et Mémoire de la Société de Chirurgie de Paris, vol. xxi., p. 148.

Digitized by Google

examined a case and clearly showed that the tuberculous lesion was limited to one kidney. A woman, aged twenty-six years, who was admitted into the Glasgow Royal Infirmary suffering from symptoms of tuberculous pyelitis of the left kidney, was first under the care of my colleague, Dr. Alexander Robertson, who asked me to make the examination. Subsequently the patient was transferred to the surgical ward, under the care of Dr. Robertson's corresponding surgeon, Mr. H. E. Clark, who successfully operated by lumbar nephrectomy. Previously to making the examination by the ureteral catheters it was noted that the urine was decidedly below the normal in quantity, that it had a specific gravity of from 1015 to 1020, and that it contained albumin and pus, the former in larger quantity than could be accounted for by the amount of the latter. The examination of the urine separately from the two kidneys gave the following results:—

TABLE II.—*Showing the Characters of the Urine from each Kidney.*

—	Right kidney.	Left kidney.
Appearance	Clear and pale in colour; on standing for 6 hours only a deposit of mucus and a few epithelial cells.	Dark straw colour: clouds on standing for 6 hours, with an abundant deposit.
Reaction	Neutral.	Alkaline.
Albumin	Very slight trace.	1·805 per cent.
Hæmoglobin	None.	1 in 8000.
Tube-casts	None.	None.
Microscopic examination	Slight deposit of epithelium and mucus; no blood, pus, or tube-casts.	Abundant deposit of pus, with triple phosphates; a few blood corpuscles and spheroidal epithelium; no tube-casts.

No tubercle bacilli could be discovered in the deposit from the urine, but after the kidney was removed it was found to be characteristically tuberculous. The patient made a good recovery.

CASE 15. *Profuse hæmaturia with slight pain in the left kidney recurring thrice; no other deposit in the urine and no swelling in the lumbar region; apparent recovery for two years, followed by a relapse of the symptoms and a swelling in the left lumbar region; muco-purulent deposit in the urine and tubercle bacilli; no vesical irritation.*—A young woman, aged eighteen years, consulted me in September, 1893, on account of a profuse hæmaturia which had occurred a fortnight previously. No reason could be assigned for the onset of the bleeding and it was unaccompanied by any pain over and above a sense of fulness and weight in the left renal region. A careful examination of the urine failed to reveal any abnormal constituents beyond a small trace of blood, but the hæmaturia had practically disappeared at the time I saw the patient. Three months after this first hæmorrhage a second attack, not so profuse or so prolonged as the first, occurred and two months thereafter a third attack, all without any concomitant symptoms. On account of the difficulty in forming a diagnosis an examination of the bladder was made during the last attack and blood was seen issuing from the left ureter in a distinct cloud; it was therefore evident that the hæmorrhage was of renal origin, but as there were no symptoms pointing to the nature of the malady complete rest in bed was enjoined and the patient made what was regarded at the time as a complete recovery. Two years after the first hæmorrhage a fourth hæmorrhage occurred; this was associated with considerable pain in the left lumbar region and a distinct swelling could be made out by palpation. Examination of the urine two weeks after the hæmorrhage occurred showed it to contain a deposit of muco-purulent material as well as blood corpuscles, and on microscopic examination tubercle bacilli were discovered. Still there were no symptoms present indicating any irritation of the bladder. The temperature was now elevated for the first time and the patient suffered from night-sweats, but there was no emaciation, loss of appetite or serious constitutional disturbance.

This case illustrates to some extent the analogy between tuberculous lesions in the kidney and those in the lungs. It is by no means an uncommon occurrence to meet with cases of profuse and frequent hæmoptyses long prior to the development of physical signs of tuberculous phthisis, so also in renal tuberculosis hæmaturia may be present as a premonitory symptom of tuberculous disease long antecedent to the development of a gross renal lesion.

CASE 16. *Hæmaturia thirteen years previously to admission and again nine years after the first bleeding; large tuberculous pyonephrosis.*—A man, aged thirty-nine years, was admitted to the Glasgow Royal Infirmary on April 28th, 1896, complaining of pain in the region of the right kidney. The patient's first trouble in connexion with the urine dated back to thirteen years before, when he had a slight attack of hæmaturia accompanied by pain over the right kidney, but these symptoms passed off in a few days. The patient had been in the infirmary in February, 1896, with hæmaturia. He first noticed blood regularly present in his urine in November, 1895. He, however, was able to continue at work until the end of January, when he came into the hospital; at that time the hæmaturia was very considerable. He said that it was only three weeks previously to admission that he noticed anything like severe pain in the right side and since the pain came on he had not noticed any blood in the urine. On examination a very distinct fulness was found in the right lumbar region. The whole space between the liver and the crest of the ilium was dull on percussion and on pressure considerable tenderness was produced. The thoracic organs and the other abdominal organs were normal, so also was the bladder. The urine contained a considerable quantity of pus and some blood and tubercle bacilli were present. The left kidney was healthy. On operation a large tuberculous kidney was discovered on the right side; it was scraped and evacuated.

In this case it is difficult to say whether or not the first hæmaturia thirteen years previously to admission was due to a tuberculous lesion, but the circumstances that nothing else was discovered to cause bleeding and that no hæmorrhage has occurred since the operation rather support the idea that it was a true case of tuberculous hæmorrhage from the beginning. Such cases as the two just recorded are uncommon and are worthy of consideration.

(c) Cystic degeneration and hydatids.—While in the early stage of cystic degeneration of the kidney urinary symptoms are generally absent, as a rule as the disease advances the urine has been found to contain albumin and finely or coarsely granular tube-casts; hæmaturia has also been noted in a considerable number of the recorded cases—I have found it in about one-fourth of the cases which I have tabulated. Sometimes the hæmaturia has been profuse, in other instances small in amount. The fact just stated differs from what is observed by Dickinson, who says, speaking of the urine: "It is characterised in most cases by the frequent admixture of blood, often so copious as to call for styptics; of 16 cases in which symptoms were present hæmaturia was prominent in 11; in some it largely contributed to death by the exhaustion it caused; in others it gave trouble through the formation of coagula." In the case about to be described the urine was never free from blood, the persistent and sometimes considerable hæmorrhages led me for some time to suspect malignant tumour of the left kidney. The character of the hæmorrhage and the circumstance that it was associated with a swelling which was steadily increasing supported this view; while, on the other hand, the fact that subsequently the right kidney became enlarged and was painful—taken in conjunction with the discovery that the hæmorrhage was from the left kidney only and that there was evidence of chronic tubular nephritis—made me doubt the accuracy of my first diagnosis of malignant tumour and inclined me towards that of cystic degeneration. The presence of hypertrophy of the left ventricle and increased arterial tension supported this view.

CASE 17. *Cystic degeneration of both kidneys; persistent renal pain, anæmia, and emaciation; hæmaturia from the left kidney only; albuminuria; granular and hyaline tube-casts; physical signs of cystic kidney on both sides; hypertrophy of the heart; death after five years from uræmia.*—A male, aged forty-six years, consulted me in 1881 when he complained of pain in both loins from which he had been suffering for the previous eighteen months. He complained of loss of appetite and occasional nausea after taking food, also headaches and giddiness; but what alarmed him most was the persistent renal pain and hæmaturia. The latter symptom had been present for seven months. At first the

Digitized by Google

quantity of blood was small in amount, being only sufficient to tinge the urine, and when the urine was allowed to stand a red deposit was thrown down which did not amount to more than from ½ to 1 per cent. in volume. When the patient had been under observation for some time a careful examination of the urine was made in order to determine the relative proportion between the amount of hæmoglobin and the quantity of albumin present in the urine, with the following results:—

TABLE III.—*Showing Analysis of the Urine on Various Occasions, with Special Reference to the amounts of Hæmoglobin and Albumin.*

When albuminuria is due simply to the presence of blood the ratio of albumin to hæmoglobin is as 1 is to 1·6. As shown by the foregoing table in this case the amount of albumin was relatively greater—namely, as 358 is to 99 or, to state it more simply, as 3·6 is to 1—that is to say, the whole of the albumin present in the urine was not accounted for by the presence of blood; indeed, not more than a fifth part of it could be properly attributed to the hæmaturia. Repeated microscopic examinations of the urine failed to show the presence of blood-casts, but on almost all occasions finely granular and hyaline tube-casts were found together with free blood corpuscles, a few leucocytes, and some epithelial cells. The urine from both ureters was examined separately at three different times and it is a fact worthy of note that while on all occasions that from the left kidney contained blood the urine from the right kidney was free from it.

TABLE IV.—*During 1884: Examination of the Urine from the Two Ureters Separately.**

——	Right ureter.	Left ureter.
Appearance	Pale straw-colour, clear; on standing for eight hours slight deposit of epithelium and a little mucus.	—
Hæmoglobin	None.	1 in 6000.
Reaction	Neutral.	Neutral.
Albumin	A trace.	Larger in amount than from right kidney.
Tube-casts	Hyaline and granular.	Hyaline and granular.
Microscopic examination	Slight deposit of epithelium and mucus, a few tube-casts, no blood or pus.	Deposit the same as from right kidney, with red blood corpuscles added.

* Silbermann's method of compressing the ureters was employed.

During the time the patient was under observation the kidneys slowly and steadily increased in size and at no time either suddenly increased or diminished even although the quantity of urine varied greatly in amount. The post-mortem report is as follows. The kidneys weighed 28 oz. and were each converted into a large conglomeration of cysts of varying size and colour and so closely packed together that it was difficult to detect any renal tissue with the naked eye, although with the microscope abundance of tubules and glomeruli could be seen. In both kidneys there was also evidence of chronic tubular and interstitial nephritis. The only difference between the right kidney and the left one was that whereas the latter was somewhat the larger the cysts in the former were not so numerous and were more deeply pigmented. The specimen is in the Royal Infirmary Museum, Series vii., No. 89.

4.—*Tumours of the Kidney.*

Hæmaturia is the most important and significant symptom of malignant disease, especially cancer of the kidney, and tumours of the kidney are nearly always malignant. It is true various forms of fibromata have been recorded and occasionally an osteoma, a lipoma, an adenoma, and cases of a papilloma have been published from time to time, but they are very rare. In tumours of the kidney hæmaturia takes place in about 25 per cent. of cases in children; these are always, or almost always, sarcomata. In adults about 20 per cent. of the cases of malignant disease present hæmaturia as a prominent symptom; these are divided between the sarcomata and the carcinomata. In carcinomata alone 75 per cent. of the cases present hæmaturia as a prominent symptom. Hæmaturia of malignant disease is rarely severe at its early stage, although cases have been recorded in which profuse bleeding occurred. As a rule, however, it is only as the disease advances that the loss of blood attains to such an amount as to form a distinct deposit. When the hæmorrhage has commenced it is more profuse, is steadily progressive, and less transient than when due to other causes, and is generally spontaneous and continuous, although at intervals liable to aggravation. Clots frequently form and may cause obstruction to the escape of urine through the ureter, bladder, or urethra (Case 8). The presence of organised constituents in the urine, such as epithelium, tube-casts, &c., is of comparatively little diagnostic value, although by some observers considerable importance has been attached to the presence of so-called "cancer cells." As a matter of fact, however, cells resembling those of a cancerous growth seldom find their way from the kidney to the bladder; in this opinion I entirely agree with Dickinson, who says: "I have met with not a few in which a discharge of cells of epithelial type, together with blood, has been supposed to indicate cancer of the kidney, but not with one in which this supposition has been verified. If I am told that such a one is passing 'cancer cells' in the urine I conclude that, whatever his disease may be, it is not cancer of the kidney. A deposit consisting of blood-corpuscles, mixed, if with anything, with indefinite sanguinolent material, and that constant, during repose as well as under exercise, is a sign in this respect of more meaning. It is to be borne in mind that a fungating tumour of the kidney is less often cancer than sarcoma, the cells of which, associated as they are with connective tissue, are not to be easily and abundantly shed, while even should they reach the urine they are, at least in the small-celled varieties which are the more numerous, too small to attract attention when confused with red and white blood corpuscles."

In desquamative catarrh of a mucous surface the epithelial cells are shed in large numbers and mingle with the secretion. From what has been written by some observers one would be led to the conclusion that they believed that this process of separation was all that happened to the epithelial cells and that these were thrown off from the mucous surface in much the same form as they presented during health. This is not so. When a mucous membrane is inflamed the epithelium becomes granular and undergoes a process of softening so that the cells are capable of taking on the most varied forms and of throwing out prolongations. This is most marked when the superficial cells are rapidly thrown off and being replaced quickly by means of regenerative multiplication of the deeper cells. Hence the catarrhal secretion may contain epithelium in all stages of development, from round cells resembling pus corpuscles to caudate cells similar in appearance to those described as being characteristic of exudation from the renal pelvis. I do not deny that, for example, in vesical catarrh groups of tessellated epithelial cells of circular form are sometimes significant and that in pyelitis, flattened, laminated, caudate epithelial cells may be often more abundantly present in the

Digitized by Google

urine than when the renal pelvis is not involved in the inflammation, but the point I desire to impress is that the diagnostic significance of individual loose cells is of no more value than is the observation of single epithelial cells removed from a tumour. To diagnose pyelitis from the appearance of the cells in the urine is no more justifiable than the diagnosis of a cancer from a few isolated cells detached from a growth. If the mucous membrane was shed in small shreds or in casts, with the epithelium adhering, then the microscope might aid in the diagnosis; but when the histological relationships of the cells are lost so also is their significance. The presence of loose epithelial cells does not indicate the nature of the renal affection, but if small portions of the neoplasm are discovered in the urine their examination under the microscope will clear up the diagnosis.

In malignant disease of the kidney when the tumour is limited to the substance of the organ the urine is usually perfectly natural, but when the neoplasm has invaded the pelvis blood-casts, epithelium, and portions of the growth may appear in the excretion. In the early stage of the disease, however, even before any abnormal constituent can be detected in the urine, the patient may experience considerable difficulty in micturition, probably the result of a reflex nervous excitement. In some cases of malignant disease the hæmaturia is a delayed symptom. This is especially so in cases of sarcomata. An enormous, soft, round-celled sarcoma may exist and develop without hæmaturia or any other disturbance in the secretion indicating the locality of the disease, as, for example, in the following case.

CASE 18. *Large, rapidly growing, round-celled sarcoma of the left kidney without any abnormality in the urine or symptoms pointing to renal tumour; physical signs, however, characteristic.*—A child, aged three years, was admitted to the Glasgow Royal Infirmary on April 2nd, 1897. The patient was pale and emaciated and the left side of the abdomen was occupied by a smooth, rounded swelling, highly elastic but non-fluctuant in the lumbar region, and passing forward to within one and a half inches of the umbilicus. The swelling could be distinctly felt extending between the margin of the ribs and the bones of the pelvis and over the entire area of increased resistance a dull note was elicited on percussion. The swelling was firmly fixed and the patient did not complain of pain or discomfort further than could be explained by the pressure of the new growth. The history of the case showed that the swelling was first noticed three months previously to admission, but at that time it was extremely small in size, so that as far as it is known the tumour was of not more than two and a half months' or three months' growth. No abnormal constituents were found in the urine at any time nor did the patient complain of any vesical irritation. Operation revealed the presence of a huge round-celled sarcoma which was removed by abdominal nephrectomy.

I have seen two other cases of malignant disease of the kidney—one a spindle-celled sarcoma, the other a carcinoma where hæmaturia was noted to have been present during the whole course of the case.

Sometimes the diagnosis of malignant disease is rendered difficult by the presence of a calculus in the diseased kidney. The following case I brought before the Glasgow Pathological and Clinical Society in 1895.

CASE 19. *Renal calculus with symptoms of ten years' duration; pain in the loin; repeated hæmaturia with cessation of symptoms for considerable periods after treatment by rest, thereafter followed by symptoms pointing to malignant disease; calculus and epithelioma of the left kidney.*—A man, aged fifty-six years, was seen by me first on Dec. 12th, 1884, and at that time he gave a history of his illness which clearly pointed to renal calculus in the left kidney. He said that about ten years ago he began to suffer from a dull, aching pain in the loin accompanied by a sense of weight on the affected side when he was occupied at his work, that of a marine engineer. The pain was inconstant but as a rule it was aggravated by any sudden movements of the body, such as jumping, running, or sudden change of position in bed. The pain also varied with posture; when he lay upon his left side the pain was relieved, while if he stood, or lay upon his right side it was increased. At this time the abnormal sensations were strictly limited to the left side. Within six months of the onset of the pain he commenced to suffer from frequent micturition, with pain in the bladder, and at the same time he noticed that the urine contained small quantities of blood. The bleeding was usually accompanied by pain and as a rule it was increased by movements of the body, but sometimes several hours or even days might elapse between the exertion to which it was referred and the appearance of the blood in the urine. The blood was intimately mixed with the urine when passed, but if the urine was allowed to stand for a few hours the blood corpuscles gradually separated as a deposit and left the supernatant urine clear. At this time the urine was acid. The patient was a very intelligent man and I could rely thoroughly upon his statements. He said that the medical men whom he had consulted told him that he suffered from a stone in the kidney and that they had reported his urine to be free from albumin and pus. The symptoms of renal calculus, after being in abeyance for three years, recurred in 1878. When I saw him in 1884 he was suffering very severely from hæmaturia, together with sharp pain in the left renal region. Considering the history above recorded the diagnosis seemed to me to lie between renal calculus and a stone in the bladder; the general course of the hæmaturia was strongly in favour of the hæmorrhages being renal rather than vesical. I ordered the patient to take rest for a week and at the end of that time the pain was greatly relieved and the hæmorrhage had almost entirely disappeared, but the urine on examination was found to contain not only blood but also a considerable quantity of albumin and a few tube-casts; these were present in acid urine and could be readily separated by a centrifugal machine, but the tube-casts did not deposit readily, and if the urine became alkaline they disappeared, probably by solution. The question placed before me by the patient was whether his case was a suitable one for operation or not, and the patient came to me for the special purpose of being informed whether one or both kidneys was diseased, as he had been told by his medical attendant that the urine from each kidney could be examined separately. After some trouble I succeeded in catheterising the ureters and while I found that all the blood came from the left kidney the urine from the right kidney contained both albumin and tube-casts. I consequently advised the patient against an operation, but prescribed what I considered suitable treatment for his relief. At this time there was no evidence of tumour in the renal region. The patient was directed to take as much rest as possible and instructions were given him as to his general health. I did not see the patient again until June, 1885, when he presented himself to report progress. His general appearance was markedly improved and he told me that for the previous three months he had not observed any blood in the urine, although he suffered from occasional pains in the left renal region. These pains were, however, less frequent and less severe than in the latter months of 1884; still there were no signs of swelling in the loin. The next time I saw the patient was in November, 1886, when I observed a great change in his appearance. He was greatly emaciated, pale, and found a difficulty in walking even a short distance. He told me that he had almost no appetite and frequently when he took food it was rejected. About four months previously to his last visit to me he had a very severe and prolonged attack of hæmaturia and sometimes clots were formed which caused obstruction to the escape of the urine from the ureter or from the bladder. The pain was also more intense and more constant, and instead of being dull or paroxysmal, as in former times, it was now more lacerating and the area of distribution of the pain was greater; instead of being limited to the hypogastrium or the lumbar region it now extended down the left thigh, across the abdomen, and to the left shoulder. The urine in addition to tube-casts deposited large epithelial cells which were bound together more or less by blood-clot. Now for the first time a distinct swelling was observed in the left loin, the tumour could be distinctly felt through the lumbar muscles, and, with one hand in the lumbar region and the other in front, a smooth, solid swelling of about twice the size of an ordinary kidney could be made out. The tumour was firmly fixed and painful on pressure, the percussion in the loin was dull as far as four and a half inches from the spine, and this percussion was not varied by the position of the patient.

The two cases last described are exceptional, the one in the circumstance that a huge malignant tumour developed without giving rise to any characteristic symptoms, and the second in that a renal calculus in the pelvis of the kidney by producing local irritation probably induced the formation

Digitized by Google

of an epithelioma. In the great majority of patients suffering from tumour of the kidney the first warning which the patient receives of the presence of disease is a profuse hæmaturia (see Case 8), sometimes induced by slight violence but in most instances coming on spontaneously; probably the most profuse renal hæmaturiæ are those met with in cases of malignant disease.

Glasgow.

A CASE OF INTRA-THORACIC TUMOUR WITH SECONDARY GROWTHS IN THE BRAIN AND ALTERNATE PARALYSIS.

By WILLIAM CECIL BOSANQUET, M.A., M.D. Oxon., M.R.C.P. Lond.,

FORMERLY FELLOW OF NEW COLLEGE, OXFORD; ASSISTANT PHYSICIAN TO THE VICTORIA HOSPITAL FOR CHILDREN; MEDICAL REGISTRAR, CHARING-CROSS HOSPITAL.

THE following case appears to be worthy of record as an example of a somewhat curious combination of conditions giving rise to crossed paralysis. I have to thank Dr. Mitchell Bruce, under whose care the patient was, for his kind permission to publish these notes.

A married woman, forty-three years of age, was admitted to Charing-cross Hospital on April 7th, 1897, suffering from cough and weakness of the left side of the body and the right side of the face. Her mental condition rendered it difficult to obtain a satisfactory history of her illness, but from her own account, supplemented by that of her friends, it appeared that she had never been quite well since an attack of "influenza" in 1892 and that she had suffered from cough since Christmas, 1896. She had been actually confined to her bed since Feb. 22nd, 1897, when she had an attack of congestion of the lungs. A fortnight after this (March 8th) her mouth became drawn over to one side and she was unable to move her left arm. There was at the same time loss of feeling in this limb, as was shown as regards thermo-anæsthesia by her holding in her hand an egg which had just been taken out of boiling water. This attack seems to have come on suddenly, as she was found in this condition by her husband, who had left her in her usual health a few hours previously. A week later (March 15th) she was found on the floor unconscious, having apparently fallen out of bed. She was supposed at the time to have fainted as she quickly recovered consciousness, but the paralysis was found to have increased in the affected arm and the left leg also was now partially paralysed. No further sensory disturbance was noticed and the original loss of sensation had by this time passed off. With regard to her previous history little could be ascertained. She had had four children, the last ten years previously, and they were all alive and well. In the last five years she had had three miscarriages. After the death of the patient her husband stated that he believed that she had undergone an operation, apparently gynæcological, in either Guy's Hospital or the Middlesex Hospital, but as he could not fix the date of this even approximately no record of such an operation could be obtained.

On admission to hospital the patient appeared to be a fairly-nourished woman, but looked prematurely aged. Her face was flushed and her expression was melancholy and anxious. While at rest the left corner of the mouth was higher than the right and on attempting to smile or to show her teeth the lower part of the face on the right moved less than the other side. The pupils were equal and reacted normally to light and accommodation. The tongue was protruded with great difficulty and tended slightly to the right side. Her mental condition appeared to be dull and her memory was impaired. Her speech was indistinct and hesitating. She had no difficulty with any special letters and could repeat words at dictation quite correctly but not write them. Told to write "Come here," she put "Mer"; for "To see" she put part of her name and address. She could not read correctly and left off reading a simple book because she could not understand it. In the left arm the grasp and other movements were distinctly weaker than in the right limb, but the range of movement was good or both sides. No sensory defect was discoverable in either arm nor could any deep reflexes be obtained. In the legs all movements of the left extremity appeared to be sluggish and strengthless, but sensation seemed everywhere to be normal. The knee-jerks were equal and not markedly increased. The plantar reflex was more marked on the left side and here there was also ankle clonus. The patient passed urine under her, apparently from mental defect. This had not occurred before admission. In the chest movements of respiration were good—36 to the minute—and the apex beat was in the normal position. The first sound of the heart was short and sharp, but there was no bruit audible. The pulse was regular, the arteries were cord-like and slightly tortuous. Behind there was dulness on percussion at the right base extending upwards nearly to the angle of the scapula, with absence of breath sounds and diminished vocal resonance and fremitus over the dull area. The abdomen was rather full with well-marked lineæ albicantes; nothing abnormal could be made out on palpation. The urine was acid, of specific gravity 1024, and did not contain albumin or sugar or any casts. The optic discs were normal. The patient's mental condition gradually improved throughout the following week and the weakness of the limbs appeared also to diminish. She was treated with an acid mixture containing some arsenic and strychnine. On the 14th she complained of indigestion with some pain in the epigastrium and left iliac region. The mixture was discontinued and a medicine containing iodide of potassium was given on account of the history of miscarriages. On the 16th there was pain in the left supra-clavicular region with slight fulness and tenderness, and on the following day the left shoulder, including this region and the upper arm, were swollen and œdematous. The œdema gradually extended to the forearm and back of the left hand, and pitting could be obtained over both clavicles and the whole of the left side of the thorax. There was no œdema of the legs or back and no ascites. The breath sounds were very harsh over the whole front of the chest and were bronchial in character over the upper lobe of the left lung. There was impaired resonance on percussion over both upper lobes, especially the left; the physical signs at the right base still continued and there was now a very similar condition found at the left base also. Enlarged veins were visible over both supra-clavicular regions and the skin here appeared to be slightly reddened. The patient still complained of indigestion and the action of the heart became slightly irregular. During the next few days the œdema of the arm diminished to some extent, apparently owing to the establishment of a collateral circulation, as the enlargement of superficial veins became more marked. On the 23rd the patient complained of pain in the calves of both legs and there was some œdema on the right side over the gastrocnemius. There were also dyspnœa with slight cough and considerable epigastric pain and flatulence. The latter was relieved by bismuth mixture and the patient from this time forward was given scarcely any solid food. On the next day an erythematous rash appeared on the abdomen, distributed in streaks. There was still some pain in the epigastrium and the recti here were tense and resistant. The right forearm was now also œdematous and a cord-like thrombosed vein could be felt just below the internal condyle of the humerus; a few days later there was also thrombosis of the enlarged superficial veins on the chest and the upper part of the abdomen. On the 29th a distinct friction sound was audible over the base of the right lung behind and there was ægophony on both sides in the inter-scapular region. The dyspnœa was now very marked and the patient was in considerable distress. The right side of the chest was therefore aspirated and 36 oz. of slightly turbid yellow fluid were withdrawn. This was found microscopically to contain a certain number of leucocytes and some large (epithelial?) cells, the latter often aggregated into rounded masses. The breathing improved in consequence of the operation, but the œdema of the arms continued and that of the legs increased. The enlarged veins on the chest and abdomen became still more prominent and the current in them appeared to oscillate, flowing equally in both directions from above and from below. On May 5th the fluid in the right pleura had reaccumulated and was again withdrawn with the aspirator. There was now œdema of the back and a tendency to cyanosis. A mass could be felt in the epigastric and umbilical regions lying somewhat deep in the abdomen and the liver was palpable below the costal margin. The patient's condition gradually became worse; she was restless and slept badly. An offensive vaginal discharge appeared, but

Digitized by Google

on examination nothing to account for it was found. Her appetite was bad and she complained of a foul taste in the mouth; there was still considerable dyspnœa. The left pleural cavity was accordingly aspirated, but little improvement resulted, and the patient died on May 18th. On the day before her death the stools were noticed to be very black in colour, suggesting hæmorrhage.

Necropsy.—At the post-mortem examination, made by Dr. William Hunter, the glands in the mesentery and along the aorta were found to be much enlarged and the lymphatics of the pelvis were dilated so as to resemble the condition found in filariasis. The left ovarian and renal veins and the right common iliac vein were thrombosed and impervious, the liver was fatty, the kidneys were normal, and the spleen was shrunken and atrophied; the intestines contained altered blood but were themselves healthy. On the lesser curvature of the stomach was an ulcer 1½ in. in diameter, cleanly punched out and circular in shape; the viscus was partially filled with altered blood. The vagina and body of the uterus were normal; the cervical canal was inflamed and contained a sanguineous discharge. No trace of any operation on these parts could be found. The right pleural cavity contained over two pints of blood-stained serum; both the visceral and parietal layers of pleura were studded with small nodules of vascular new growth. The heart was healthy; the pericardium contained several ounces of bluish serum. The lower lobe of the left lung was in a condition of hypostatic congestion and showed some old cicatrices. In the right lung the lower lobe was collapsed and puckered into a mass of new growth which occupied the lower posterior margin. The growth was pigmented and caseous in parts. The glands on the left side of the neck were much enlarged. The internal jugular and subclavian veins were thrombosed at their junction to form the left innominate vein, and this vessel was also blocked at its junction with the vena cava and contained a quantity of milky fluid, apparently accumulated chyle. Within the cranial cavity there was found some increase of cerebro-spinal fluid at the base of the brain. There was a nodule of growth $\frac{5}{8}$ in. deep by $\frac{5}{8}$ in. wide, and 1 in. in antero-posterior diameter at the vertex close to the longitudinal fissure on the right side, occupying the posterior and inner part of the superior frontal and part of the marginal convolution. A second small growth $\frac{1}{4}$ in. in diameter was visible in the posterior limb of the right internal capsule, and a third nodule $\frac{1}{10}$ in. in diameter on the external capsule at the edge of the lenticular nucleus, just on a level with the former growth. A fourth tumour $\frac{3}{8}$ in. in diameter occurred in the centrum ovale just beneath the cortex on a level with the posterior end of the caudate nucleus. All these lesions were in the right hemisphere. On the left side no new growths were found, but there was a small patch of softening of about the size and shape of a grain of wheat, vertically placed, situated on the anterior limb of the internal capsule. The medulla and pons were normal and there was no apparent disease of the cerebral vessels. No descending degeneration was found in the pons or crura. The spinal cord was unfortunately not preserved. Microscopically the growth was carcinoma consisting of large glandular cells and little intervening stroma.

Remarks.—On the patient's admission the symptoms of crossed paralysis suggested some lesion of the pons, but the slightness of the affection made it difficult to conjecture what the exact nature of this lesion might be. Later, the paralysis appeared to improve and what was left of it was merged in the general weakness resulting from the grave condition of the patient. Signs of intra-thoracic pressure were now the prominent features of the case; the pleurisy, the character of the fluid withdrawn, and the venous thrombosis in various parts of the body pointed to the probability of malignant disease. The gastric ulcer found at the necropsy was not diagnosed during life, though the existence of malignant disease of the stomach had been suspected owing to the emaciation, the epigastric pain and tenderness, and the flatulent dyspepsia. The exact seat of the original cancer could not be determined. The first symptoms were caused by the cerebral growths, which were multiple and evidently secondary. The growth in the lung was the most advanced, and the early occurrence of cough, which had been complained of before admission, might point to this as the original lesion, but the rarity of this seat of primary carcinoma makes the suggestion doubtful. No primary focus could be found in the abdomen to account for the enlarged glands there and it is noteworthy that these occurred late in the history of the case. Judging from the apparently normal condition of the uterus and appendages no severe operation could have been performed, such as might throw any light on the origin of the malignant disease.

The distribution of the paralysis seems fairly accounted for by the cerebral lesions. The large nodule at the vertex occupied part of the leg area; the growth in the right internal capsule explained the weakness of the arm and indirect pressure exerted by it on the fibres of the posterior limb of the capsule was no doubt the origin of the anæsthesia. The facial paralysis on the other side was apparently due to the minute patch of softening in the left internal capsule, but the origin of this lesion was not easily explicable. It may perhaps have been due to some small venous thrombosis, analogous to those occurring later in other parts, such as seems often to occur in malignant disease. The conjunction of the two distinct forms of lesion on opposite sides of the brain is at least unusual. Another point of considerable interest is presented by the fact that the paralysis on both sides completely or almost completely disappeared, although the organic cause of it on the right side of the brain cannot have lessened in extent and was probably actively progressing. The paralysis must be classed as "functional," due to some disturbance in the activity of the nerve-units, not to their destruction. What, however, the exciting cause of the original fits and the ensuing paralysis may have been must remain unexplained. There was no sign of any hæmorrhage into any of the growths such as might have caused a sudden cerebral disturbance. Further, there was no sign of any great increase of intracranial tension, as the convolutions were not flattened, nor was there headache, vomiting, or optic neuritis. In short, the cerebral condition in no way shortened life and had not the thoracic disease progressed so rapidly the patient might have left the hospital relieved of her paralysis, which would have remained entirely unaccounted for.

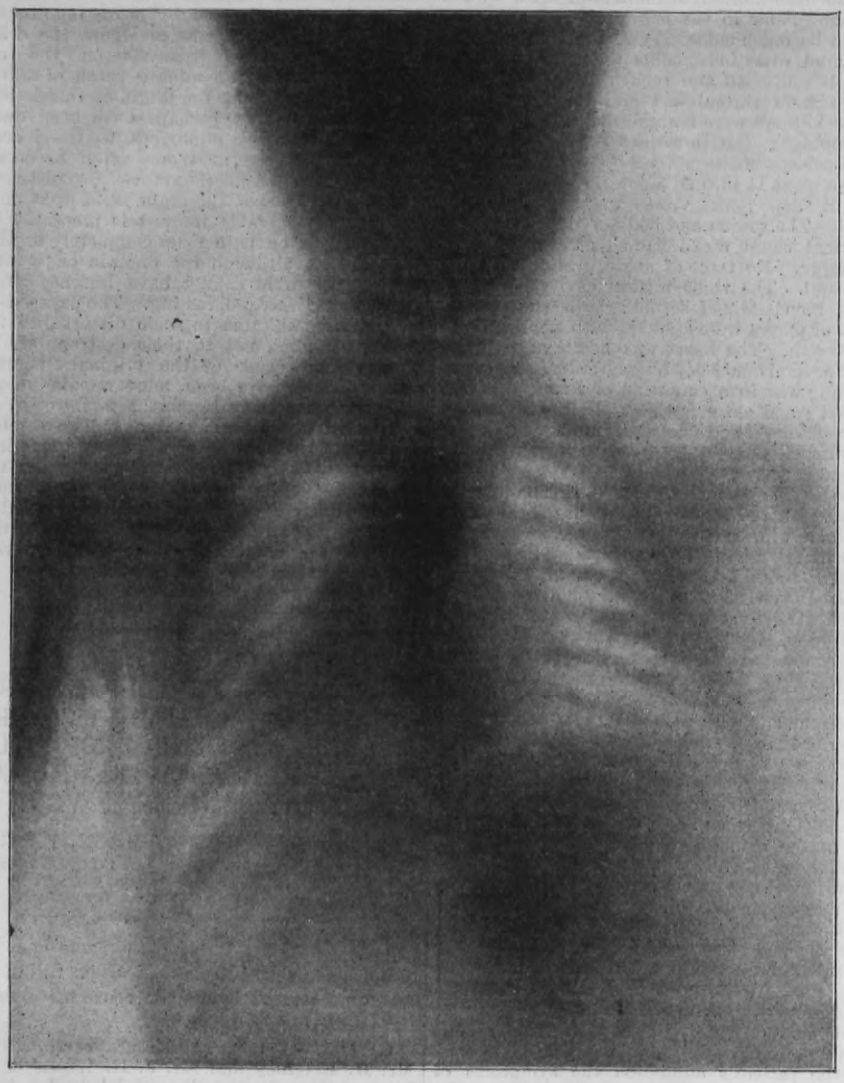
York-street, Portman-square, W.

TWO CASES OF HALFPENNIES IMPACTED IN THE ŒSOPHAGUS FOR FIVE AND SIX MONTHS RESPECTIVELY, REVEALED BY X RAYS AND REMOVED.

BY A. W. MAYO ROBSON, F.R.C.S. ENG.,

SENIOR SURGEON TO THE GENERAL INFIRMARY AT LEEDS; PROFESSOR OF SURGERY IN THE YORKSHIRE COLLEGE OF THE VICTORIA UNIVERSITY.

THE following unusual cases came under my observation quite independently of each other within the same week and were treated by me on consecutive operating days in the Leeds General Infirmary.



CASE 1.—A boy, aged four years, was sent to me by Mr. H. Keighley and Mr. J. H. Woods of Batley with the history that six months previously he had swallowed a halfpenny and at the time had almost died from suffocation, which was prevented by his mother's presence of mind in pushing the coin beyond the entrance of the larynx by means of her finger. The coin was supposed to have passed into the stomach, as although he had some pain in swallowing there was no actual obstruction to the passage of food. Some weeks after he began to have pain in his neck, to have difficulty in swallowing, and to hold his head stiffly to the left side, almost as if he had caries of the cervical spine. He began to lose flesh and to look ill. It was then decided that he should be photographed by the Roentgen rays. The photograph (by Messrs. Reynolds and Branson of Leeds) was brought with the patient and it shows (*vide* figure) the coin impacted in the œsophagus at a point opposite the pericardium, where it would also be in close contact with the left pleura and with the aorta. I decided to attempt its removal through the patient's mouth, and that failing I obtained permission to perform œsophagotomy. It was explained to the parents that there might be risk of hæmorrhage or perforation in removing the coin from its bed, but they decided to accept all eventualities. On Feb. 18th, the patient being under ether, I inserted the coin-catcher invented by the late Mr. Sam Smith, and at the

Digitized by Google

first introduction I withdrew the halfpenny without any difficulty. It was much corroded and covered with greenish-black material. Nothing untoward occurred and the boy left the infirmary quite well the next day.

CASE 2.—The patient was also a boy, aged five years, and the photograph showed the coin in the same position as in Case 1. The same treatment was adopted and with the same result.

The "coin-catcher" is a most ingenious instrument with which I have removed coins recently swallowed on other occasions, and as it is so simple in action and so painless in application it should in any doubtful case be applied as soon as the patient comes under observation. In cases of doubt the new photography can be employed with great advantage, as shown in the two examples I have related. I noticed a report in one of the journals lately that in a similar case, where the coin had been swallowed only a short time previously, œsophagotomy was performed without any attempts being made to remove it through the mouth. My experience would lead me to conclude that such an operation should rarely be necessary and could only be justifiable after the simple means I have related had been thoroughly tried and had failed.

Skiagram showing impaction of halfpenny in the œsophagus opposite the pericardium.

Leeds.

NATIONAL SOCIETY FOR EMPLOYMENT OF EPILEPTICS.—The annual meeting of governors was held on July 11th at the Society's offices, 12, Buckingham-street, Strand, the chair being taken by Mr. E. Montefiore Micholls. In the report for the past year presented by the hon. medical staff it is stated that "a marked improvement has been noted in the majority of cases at the Chalfont Colony," this improvement being especially pronounced in the case of the women colonists. The report of the Executive Committee refers to the rapid growth of the Colony as evidenced by the fact that besides one Home for twenty-four colonists recently completed but not yet occupied four others are now in course of erection, the cost having been provided by contributions for this specific purpose. "Yet the increase of accommodation," it is stated, "does not keep pace with the increase in the number of candidates for admission. This constant development and expansion is therefore clearly a necessity, but it is not always realised that every new Home erected at the Colony creates new wants; on the contrary, these extensions lead to the impression that existing wants have been more than adequately supplied." The result is "that the flow of generosity has been checked when the need for it is greatest," and the gravity of the financial position has led H.R.H. the Duke of York, as President, to issue a special appeal on behalf of the society for the sum of £7000 for certain immediately necessary purposes detailed in the report.

A CASE OF PEMPHIGUS SERPIGINOSUS.

BY ROBERT Y. AITKEN, M.D. GLASG.,
SENIOR HOUSE SURGEON TO THE BLACKBURN AND EAST LANCASHIRE INFIRMARY.

THE following case was a typical example of a rare form of a rare disease. Of the English text-books on medicine which I have consulted Fagge's is the only one in which a reference to the disease is to be found. It is not mentioned in two of the most recent English works on skin disease. As pemphigus only occurs once in about 400 cases of skin disease this serpiginous variety must be exceedingly rare. The description given by Fagge is so accurate that it can hardly be improved upon. He says: "The bullæ, which are small, are seen on the advancing border of a considerable area of skin formerly the seat of others which have disappeared." He adds that "when first seen in this later stage it might well puzzle an observer."

A girl, aged five years, was admitted to the Blackburn and East Lancashire Infirmary, under the care of Dr. J. M. H. Martin, on March 25th, 1898. She was the eldest of three healthy children. There was no suspicion of a syphilitic taint. Till the onset of the present trouble the child had been quite healthy. From the mother's account it appeared that the disease began in the skin of the cheek near the angle of the mouth sixteen months ago. The child did not complain of itching till the blisters were well developed. As the first blisters dried up others appeared and the disease extended to the neck and chest. Later the disease appeared on the arms, and six months from the commencement it was noticed on the groins and in front of the ankles. The arms were almost well when the eruption appeared on the legs, but they became worse afterwards. When the child was first seen she was in the condition shown in the illustration. The mother stated that the largest blister she noticed was quite an inch in diameter and they varied from this size down to small vesicles. There was no elevation of temperature and all the time the eruption was coming out the general health of the child did not appear to suffer much. This is not unusual in ordinary pemphigus. In the way of treatment local applications of various kinds were tried without success. I may say that she had been under treatment for months at home. When the diagnosis was made arsenic in the form of Fowler's solution, in 4-minim doses thrice daily, was prescribed. Within a week improvement had begun and at the end of a month only a deep red stain marked the seat of the eruption. I report the case because of its rarity and to show the therapeutic value of arsenic in the disease, as Hebra wrote that he knew "of no internal medicine which has proved efficacious against pemphigus." I am indebted to Dr. Martin for permission to publish the case.

Blackburn.

From a photograph of the patient. The bullæ and scarring are well seen on the right thigh, left leg, and left arm.

THE LORD CHIEF JUSTICE ON THE MEDICAL PROFESSION.—At the Bristol Assizes which were held recently the Lord Chief Justice of England in alluding to the medical profession remarked that he thought there was no profession in the world which rendered more entirely gratuitous service than the members of the medical profession and added that so far as his experience went there were not the sordid considerations in this profession which were present in others.

VITALITY:
AN APPEAL, AN APOLOGY, AND A CHALLENGE ADDRESSED TO BROTHER PRACTITIONERS.

BY
LIONEL S. BEALE.

(*Continued from page 1615, June 11th.*)

I APPEAL with hope to rising biologists having good eyes and understandings and lissome fingers to do their best, and quickly, to confirm or disprove anatomical details brought under our notice during the last forty years or more. Many broad questions of the greatest general interest and of wide application are still undecided—questions which are well worthy of further careful investigation by new methods of inquiry different from those usually followed. And I trust that observers, not only in Europe and America, but the young workers at microscopical investigation in India, Australia, and Japan, where there are many forms of life very different from our own, will help in endeavouring to set at rest some of the most difficult questions which have long resisted our best efforts, but which are certainly not beyond our powers and means of minute investigation. For example, concerning the general arrangement of the most delicate nerve fibres distributed to various organs of sense, to sensitive surfaces, to muscular fibres, and their exact relation to the tissues and bioplasm they influence, we have still much to learn. It is not only as regards minute anatomical detail that we require more complete knowledge, but some general questions with reference to vital action, tissue formation, and the precise action of some of the most important tissue arrangements in the body, not to speak of the question of the nature of mental work, are still open to inquiry. Are not very different and often incompatible doctrines entertained and taught by rival authorities? Microscopical investigation may even yet yield results of philosophical significance.

But to form correct views we must not be content to study only the fully formed tissues of adult organisms, but must endeavour to form an accurate conception of the several stages through which tissues pass from the first indications in connexion with the bioplasm or living matter to the fully formed state when much of the living matter of the early period of development has completely disappeared, and the tissue exhibits structure and performs functions belonging to a category different from that in which the living matter and its action must be placed.

It must I venture to think be admitted that not a few of the specimens of tissues mounted in Canada balsam display little more than the distorted skeletons of dead tissues variously modified by the particular mode of preparation to which they have been subjected; and where fine nerve-fibres are the objects studied the appearances are often open to more than one interpretation. Long ago many of us being impressed with such difficulties endeavoured to gain some advantage by proceeding on different principles. The tissues, always moist in their natural state, were examined in water in which various matters were dissolved to prevent decomposition of the tissues and to render them more transparent, in the hope that their structure and various anatomical or other constituents might be more clearly discerned. The process of preparation I was led to adopt was fully described in communications to the Royal Microscopical Society and published in their Transactions and afterwards in my books. Many of my specimens were shown in class and at my lectures delivered at the Royal College of Physicians of London. My views were fully explained in the Lumleian Lectures for 1875, and afterwards published.[1]

In examining many sections of soft complex tissues mounted in Canada balsam we must bear in mind that when in the living organism they were not compressed and matted together and pressed against one another, as seen in the balsam preparation. Though in living nature elementary parts are near to one another, each is supported and surrounded by fluid which by the action of the bioplasts is always in slow movement and gradually undergoing changes in its composition. Thus the several component parts are protected from injury and undue pressure, each is allowed free action, and at the same time preserved in a healthy condition by the free escape and removal of products of disintegration. This is probably what we should discern if it were possible to examine during life with high magnifying powers the ultimate ramifications of the nerve fibres and their relation to neighbouring tissue elements. Not only so, but from an early period of life onwards we should see suspended in the interstitial fluid minute particles of bioplasm like those present in the blood, lymph and chyle which live, grow, multiply, and after forming various substances die, the various substances resulting from death being dissolved and probably then taken up by other kinds of living matter. These considerations long ago led me to think that much more would be made out if a plan of examination could be devised by which media miscible with water in all proportions and of high refracting power, capable alike of dilution and concentration, were alone employed in preparing all the structures of man and other organisms for microscopical examination under high powers. The process was gradually improved and was found applicable to minute investigations into the structure and formation of tissues of all organisms, whether simple or complex, including plants, under the twenty-fifth-of-an-inch power made for me by Powell and Lealand in 1860.

After much careful work according to various methods at that time in use on the tissues of a variety of organisms, and efforts to trace the changes which occurred in their development and formation I discovered, like many other observers before and since, that the very points of all others which I desired to make clear, were the most difficult to decide and several were left doubtful. One required a process equally suitable for the investigation of all structures, from those which were soft and almost diffluent to those which were exceedingly hard, as bone, tooth structures, enamel, and shell. To study the gradual formative changes in such tissues one required a thin section which included the soft growing matter, the partially formed matter, and the complete structure. To follow the fine ramifications of nerve-fibres for some distance so as to form an idea of their relation to the tissues they influenced, the preparation required to be in such a state that it could be pressed or frayed out by needles, while at the same time the adjacent textures were rendered transparent without disturbing the relations of the several tissue-elements. Then one required to see the capillary vessels and the nerves running very near to them; and, above all, the numerous bioplasts and their relation to the several tissues with which they were connected and which they had formed. And, lastly, it was necessary that the medium in which the specimen was placed should be preservative so that if needful it might be reserved, placed in fresh fluid, again and again, until it became sufficiently transparent for our purpose.

The plan I pursued was well suited for the study of bioplasm of all forms and in different situations in various animals, in insects and crustacea, and in plants, for researches concerning the structure of all parts of the nervous system, including nerve centres of every kind. In the bladder of the little green tree-frog and the thin membrane of the wing of the young bat I was able to clearly make out the arrangement of most delicate nerve fibres distributed to the tissues and to the capillary vessels, to the arterioles and to the muscular tissues.

In attempts to ascertain whether in all living nature there was evidence of any uniform system of action—of any principle which does not affect the "actions and reactions" of ordinary matter—the advantages of a uniform system of inquiry and of preparing so that everything submitted to examination might be treated in the same way must be obvious. Only upon such a plan can very different structures be compared with one another and that which was common to all in arrangement or formation determined. The determination of the directions in which growth was occurring and nutrient matter being introduced, the products of disintegration removed, were also points of importance which had to be considered in the inquiry and if possible elucidated.

The plan of investigation I have pursued is in some cases difficult to practise and I must admit is troublesome and requires much patience. It is not surprising that among teachers of microscopic investigation and those who prepare microscopical specimens for sale it has not been in favour. Great care is necessary in preserving specimens permanently and it is a little uncertain. After some years, however,

[1] "On Life and on Vital Action in Health and Disease," 1875. London: J. and A. Churchill.

Digitized by Google

many beautiful specimens of very soft tissues have been successfully preserved and very delicate tissues have retained their characters. For new investigations, however, the process certainly has very great advantages and I cannot but think that some day the principles upon which it was conducted will be recognised by many, followed out, and much improved. The mere fact of our being able to keep pieces of properly prepared tissues in strong glycerine for a length of time, not only without deterioration, but with the certainty of great improvement in transparency and in the state of the tissues for further careful investigation with high powers is conclusive. The tissues will have become after some weeks more transparent, will suffer less from pressure when applied to the thin glass in order to make them thin enough for investigation, and thin sections may be dissected or frayed out in places with needles and without the relative position of the several tissues being altered or the relations of the bioplasts to the tissue or formed matters, or to one another being in any way disturbed. A piece of a highly complex texture which had been soaking for several years in good glycerine in a well-corked bottle and kept in a cool place has provided me with beautiful specimens from which valuable and quite unexpected information was gained.

Is there a naturalist in the world who feels satisfied that the evidence so far obtained in any way justifies the inference that all living things have been derived from a small or large amount of simple "undifferentiated protoplasm," or that the constitution of any one of the innumerable organisms is adequately accounted for by attributing it to the properties of the materials of which its body is composed?

Is there a microscopical observer who believes that the formation of the wonderful structures he studies is adequately explained by the assertion that it has been built up by "molecular forces" or that the movement of a small portion of the clear, transparent matter of an amœba is to be adequately accounted for by potential energy or chemical change?

Surely the great object of studying the works of nature is to try to ascertain how they were made, how they came about, how they work. Is not this the reason why we endeavour to see as far as we can into the arrangements; why we try to increase our power of seeing and make things appear to us hundreds of times larger than they really are; why we spend hours, days, weeks, years trying to learn all we can? This, however, is not the idea which influences all or the theory upon which all scientific investigation is carried on. Even in these days of liberty and freedom of thought and work, some would condemn the microscopical observer to microscopical observation only. He is not to think, to theorise, to speculate, to conjecture; but his results are to be judged by the physicist, the chemist, the mathematician, the generaliser, and the philosopher. If his observations accord with the general views entertained by these authorities the work is approved; if not it is unnoticed or ignored. Even in our empire of liberty there always seems to be springing up amongst us just a little tendency on the part of some liberal minds to form a sort of intellectual syndicate for the purpose of deciding for the people what they ought to think, accept, believe, and teach concerning nature, just as if certain scientifics had somehow captured nature for themselves and had acquired the right to represent her and to declare precisely how she was to be generally regarded by the common people.

BIOPLASM.

The demonstration of structure and the elucidation of the precise way in which it slowly appears and very gradually acquires its characters and properties naturally leads us to endeavour to ascertain the nature of the processes at work in its production and the principles according to which they are governed, guided, and regulated. Much of our physiology of the last fifty years is a physiology of the fully-formed active tissues of the adult—tissues which consist of a considerable amount of débris which under the name of connective tissue has been gradually accumulating for years around many of the active tissues. From the time when the active tissue was first formed and began to discharge its work this indefinite tissue has been, even under the greatest advantages, steadily increasing, and as age advances it seriously impedes the free action of some of the most important tissues, particularly nerve and muscle, and it is one of the causes of that natural deterioration which increases as old age advances and which may lead to natural death.

My views on tissue formation, including the softest, consisting principally of water, and the hardest, containing very little, such as shell, enamel, ivory, dentine, horn, and nail, were published in 1860–61 and soon afterwards were translated into German by my friend, Professor Victor Carus of Leipzig. The living matter was distinguished from the formed matter in each case, the important part taken by the first in the production of formed matter shown, and the absolute difference between the living matter and matter in every other state insisted upon. These views have been recently referred to by Kölliker.[1] But unfortunately 1867 seems to be the latest reference made to any of my observations, though I have done much work since that date and have published several papers and books.

The very important question of the existence or non-existence of vitality surely ought to be seriously considered and carefully debated. For the last forty years we have had at our disposal magnifying powers of 1000 diameters and upwards, by the aid of which many new facts have been ascertained with regard to the arrangement, connexion and action of various forms of bioplasm in different organisms and under different conditions. We are certainly able to distinguish the living matter, which forms tissue from the tissue itself, which has been formed by it, and we have succeeded in proving that tissue does not add tissue to that which already exists. Tissue never forms tissue.

Many of the conclusions which I have been compelled to adopt from actual observation have been so little considered that, interested as I am in the question, it would have been long ago almost a relief to have been judged wrong and to have found that the doctrine according to which all things living are but machines had proved to be correct. A fundamental and general question of such vast interest and importance to every thoughtful person as the *Nature of life* ought not for ever to remain undecided. Naturally, many observers, like myself, have been afraid of pursuing the subject in a wrong direction, and have been hoping for a decision as to first principles by which they might be guided in their further progress in this department of natural knowledge.

It has to be borne in mind that the general evidence which has been accumulating for centuries and the minute research which has been conducted by hundreds of well-trained, naturally patient and thoughtful observers who, during the last fifty years and more, have enjoyed incalculable advantages over their predecessors as regards methods of investigation as well as instruments of research, seems to prove beyond question that if we allow our judgment to be swayed by reason we can no longer accept the dictum that "the living and the non-living are one." If this be so, how many vague though most positive assertions of like tendency must be wrecked! Indeed, is it not now certain that *living* belongs to a category from which all *non-living* must for the future be excluded? Nay, will it not ere long be generally admitted that in the whole living world *Vitality*, during the short time that it influences given particles of matter, reigns supreme, and transcends, guides and governs forces, properties and tendencies which dominate the material world?

The question of the nature of life has been well considered as regards its supposed physico-chemical aspect rather than from the side of actual knowledge, which has been gained since we have been able to study living matter and the process of tissue-construction as it occurs in the widely different organisms around us with the aid of powers magnifying 1000 diameters or more, and with other advantages our predecessors could not enjoy. But ought we not to consider whether the facts now before us justify the view that man is a mechanism or a mere chemico-mechanical apparatus? The conclusions arrived at from the physico-chemical side have been widely taught by distinguished scientific men; but has the study of the comparatively inconspicuous living matter present in all living things received the attention it deserves? The process of construction of tissue in the common living organisms seems to have been little investigated of late, considering the vastly increased advantages we who try to peer into the deepest recesses of the specks of living matter now enjoy. Surely vitality deserves more notice from calm philosophy than has yet been accorded to it.

We want enlightenment as to the very first principles—the nature of the general changes which occur—how living matter in the simplest organisms is formed—how it grows and multiplies—and the general nature and source of its powers. The great advances of physical physiology and organic chemistry still leave us in doubt as to first principles and we have much yet to learn even concerning the movements of what has been called "undifferentiated protoplasm." The movements of a portion of the structureless matter of a leucocyte, a pus or mucus corpuscle have yet to be explained and accounted for—nay, the cause of the movements of the clear, transparent matter of an amœba which it is said have been exhibited by corpuscles made of gum, water, and oil, have so far resisted the efforts of many of the most talented investigators who have had great experience in inquiries of the kind to account for on chemico-physical principles.

For years have I been trying to convince myself that the views generally accepted by the majority of scientific men were justified by facts of observation and experiment and that my widely different conclusions were erroneous, but I have not been able to obtain a scientific reasonable explanation of the movements of the colourless and perfectly structureless matter of a small and actively growing amœba from any authority, while after all the cross-examination to which I have subjected myself I have failed to shake my belief in vitality as the cause of the movement which no molecular vibrations, osmotic currents, or chemical differentiations will account for.

While much attention has been given to the general structure of all classes of living organisms, their external coverings, their internal organs, and their developmental phenomena, comparatively little notice has been taken of the millions of minute particles of structureless living matter present during their whole life in all their tissues and free in some of the fluids of the body. These are the colourless, structureless bioplasts, usually spherical, or oval, and sometimes stellate in form, from which all structure proceeds, and by the vital action of which in promoting free circulation of interstitial fluid in the very substance of all the tissues the integrity of the latter is preserved and various partially soluble substances which sometimes tend to accumulate and interfere with the action of some tissues are kept in solution. Even deposits may sometimes be dissolved and removed. Many careful investigations have been conducted by highly skilled observers upon the nerves and important results concerning nerve action have been obtained, but to what extent this "action" depends upon changes in the nerve fibre and in the bioplasm particles in connexion with all the finer ramifications of the nerves has not been determined.

This living matter, or bioplasm, part of which ceases to live, while, at the same time, other portions still living communicate their wonderful powers to lifeless matter drawn into its substance in solution in the interstitial fluid, is indeed the *only active living part of us*, for by far the greater part of all our tissues and organs consists of formed matter which cannot of itself increase and multiply, take up nutrient matter, cause it to live and communicate to non-living matter its vital powers.

This bioplasm, the least conspicuous portion of the body, is nevertheless the most important, all our tissues and organs having been derived from antecedent bioplasm and to it their formation, structure, composition, and action are entirely due. So, too, in some of the most important morbid changes the inconspicuous particles of bioplasm are concerned, and it is by the influence of air, water, food and medicines that we are enabled in many cases to promote the return to the normal state of action of bioplasm and thus to restore the healthy condition of tissues, organs, and, perhaps, of the organism generally, that had for some time, perhaps, been out of order.

Bioplasm, which generally consists of more than 90 per cent. of water, is, then, by far the most important matter in living nature and its powers are infinite. All growth, all increase in the size and number of living things, as I have endeavoured to show, depend upon it. Increase is due to bioplasm only. When a particle of bioplasm dies that particular particle can never be restored to life. Lower organisms which, though dead, are said to have been revived or revivified, have, in fact, never ceased to live—have not died.

When a complex living organism dies all its bioplasm does not die at the same moment, and in some cases even tissue formation continues for a short time after the organism as a whole has ceased to live. Even in man under certain conditions some bioplasts may be for a short time more active than they were at the moment of death. In general, the first bioplasm to die in the human subject is that which takes part in the highest functions of the nervous system—the bioplasm near the surface of the grey matter of the cerebral convolutions, which is probably concerned in those mental phenomena by which man is marked off from all lower creatures.

There is nothing in the non-living world which in any way resembles death. All that lives must die and there can be no living matter which does not cease to live, the matter not being reduced in weight by its loss—its life, as far as can be ascertained, not being changed or transformed into any known force, property, or power.

The rate at which bioplasm takes up pabulum and grows and multiplies varies greatly in different organisms and in different parts of the same organism. Generally, formative changes occur slowly; indeed, it may be said that the formation of healthy, well-formed tissue, the elementary parts of which perform their offices most advantageously for the well-being of the organism and for the longest period during life, has been laid down evenly, equably, and at a normal rate. If the process occurs too slowly or too quickly there is a departure from the normal condition detrimental in many ways.

Generally, the production by bioplasm of bioplasts, having far extending and different constructive powers, is a far slower vital process than the production of the succeeding generations of bioplasts which are evolved series after series from the first in gradually increasing numbers and of more limited vital activity. For instance, the vital orderly arrangement slowly taken up by the bioplasts of the plant, produced during the winter months and in comparative darkness from the descendants of which the so-called cells, vessels, and other structures constituting the leaf or flower that is to appear in spring are formed, is a much slower process involving much less taking up and conversion of nutrient matter, than is the growth and multiplication of the succeeding series of bioplasts the last of which takes part in the formation of the several tissues when the nutrient process is active. So also bioplasts taking part in the formation of the pollen and of the ovule require a longer time for this evolution than do those concerned in the production of leaves and the several structures of the flower and its appendages. And, indeed, all through living nature the evolution of the bioplasm from which the infinite series of bioplasts which follow in successively increasing numbers generation after generation, from which at last tissues and organs of wonderful complexity and functional activity or lasting firmness and comparative passivity emanate, requires a much longer time for its completion than does the production of the series which approach nearer and nearer to the bioplasts concerned in the evolution of tissue-producing bioplasts.

Every step we gain in our progress towards the elucidation of the nature of actual vital changes surely renders it less and less reasonable to regard these wonderful vital phenomena as being in any way akin to forces, powers, or properties of any known ordinary matter. This mysterious directing, far-seeing, purposive agency, preparing for certain far-off constructive orderly arrangements of tissues and organs with special powers of action not to be imitated, forming structures operating in, and known only by us in, the living world, must surely be something different from energy or any cosmic forces or properties of matter belonging to the material universe.

The multiplication of bioplasts, having developmental formative powers little inferior to those possessed at an early period of development, after maturity has been reached, varies greatly in different classes of organisms. Thus the adult lobster may reproduce a new claw after the removal of the old one and the lizard its tail after removal; and there are some complex organisms which increase by division, highly complex parts like head and tail being developed before the transverse division of the one organism into two takes place. In many simple organisms multiplication proceeds by division and subdivision under favourable conditions when a certain size has been attained by growth, while in man and the higher animals, even before complete maturity is reached, "cicatricial tissue" seems in many cases to represent the extent of developmental formative power remaining in most forms of bioplasm—not a limb or a finger, not even a complex nerve papilla, a villus, or a

Digitized by Google

sweat or sebaceous gland can be again developed in the situations from which these structures have been removed, there being no bioplasts of sufficiently varied and sufficiently general formative powers to reproduce them.

I think all who have examined living things and the tissues of organisms soon after death must often have remarked the general resemblance of different kinds of bioplasm; and the remarkable differences between the several species and individuals which constitute the living world. The likeness of all bioplasm, the wide differences between fully-formed organisms and tissues formed by bioplasm—and impossible in its absence—are evident through all living nature. And I think all who will consider the facts will be more inclined to attribute these differences to differences of power of the bioplasm than to any character or properties of mere matter to be disclosed by the most skilful physicist or chemist—in fact, to vitality—a power working in every particle of the living world—a factor which *cannot be seen, and which cannot be touched, weighed, or measured, isolated, or captured in any way*, but whose marvellous influence upon matter which can be taken up by living things has been handed down from living particle to lifeless matter without a single break or moment's cessation ever since the first appearance of life. A break, an interruption in the vital process, is death.

Consider but a few plants far removed in character from one another and a long distance from the country where they grew, but having very well-marked characteristics and of pretty strong constitution so as not to die immediately, which it is attempted to grow under conditions to which they have not been accustomed. From lovely Japan we have received many such and we long for more. I need only refer to palms, bamboos, maples, and aralias, which have been my delight and have lived many years in the poorest soil within a few miles of London. All came when very small, all live very near to one another and have remained in the same places since they were first planted. All have survived and were hardly hurt by the hard winter of 1895, when water placed near any part of them must not only have frozen hard, but any near the roots must have remained frozen for nearly three months without thawing once. After fourteen years three of the palms have good leaves nearly 4 ft. in width and of good substance—bamboo canes are over 12 ft. in height and the other plants are in sound health and some improve in vigour year after year. Now will anyone maintain that the individuality and great resisting power to adverse conditions, and the adaptability exhibited by these plants, so very different in these respects to many allied species, which would not have survived a single winter if placed under similar circumstances, are due to the material properties of the matter of which they are composed—to any physical or chemical characters? Is it not far more probable, nay, almost certain, that their striking power of resisting adverse conditions is due rather to remarkable vital powers handed down from living to non-living particles without interruption, perhaps for thousands of years; and is it not practically certain that if transferred to their old home they would continue well under the altered conditions and live to be as old as others of the same kind, just as we see happens in the case of some higher organisms and also due to the vital powers of the bioplasm which so far have not been scientifically explained?

Or, as another example of the wonderful vital powers of plant-bioplasm in the fully-formed organism, after serious deterioration had existed for years, when there appeared little hope of improvement, at least under conditions of life widely differing from those of their natural habitat—let me refer to some camellias, which had been deteriorating for some years under the conditions shown by experience to be fairly suitable for these plants when grown in this country. About twelve years ago the plants referred to were in so bad a state that they had been almost given up for lost. Being of no value I gladly received the patients. Knowing that they disliked sunshine and having a good rhododendron hedge in the right position I placed them in an alcove looking towards the pole-star, in peat and sand, and they have not been moved. After a couple of years they began to improve very decidedly and were evidently recovering from the prolonged tissue degeneration from which they had suffered. Their general health so far improved that they formed flower buds, few of which, however, reached the flowering stage till three or four years ago. But last April there were more than a hundred flowers on two trees—one white, the other red,—most of which were well formed and the red flowers were of good colour. Quite certain about the improvement which had occurred I obtained a still more hopeless subject, which after three or four years of almost stationary helplessness is now recovering and forming good leaves. Who will maintain that such facts are to be accounted for by physics or chemistry, or deny that they are to be explained by the gradual production of bioplasm of a more healthy character year after year?

When one considers how closely the living matter, the bioplasm, which takes part in the formation of organisms differing so remarkably from one another in general characters, and in their position among living things; and, according to chemists, the close relation between the substances obtained from it in the laboratory and the comparatively few elements present—the very large proportion of water always existing in living matter and the probable absolute impossibility of living matter of any kind existing even for an instant in a perfectly dry state—it is difficult to resist concluding that the wonderful differences between living things are due to difference in *power* rather than to difference in *matter*, or to a difference in the conditions under which life is carried on—*a power which only influences matter which comes very close to, indeed which passes into, the very substance of the living particle*. The marvellous active power has been transmitted without loss, without one break or fault perhaps during thousands of years. In some cases it seems to be modified, we know not how or why, but powers of modification, like other attributes of vital power, are obviously not unlimited, though the limits within which modification in power can occur without cessation of vital power, cannot be accurately ascertained. The transmission of vital power and the increase in the number of living particles seems to vary according as the surrounding conditions are favourable or not, the power being without limit, though it may cease for ever at any moment. In living nature likeness never reaches identity, and any two forms, however closely they resemble each other, can in nearly all cases be distinguished. Each one of thousands of leaves could at once be identified as belonging to a particular tree, but it would probably be impossible to find two among many thousands which did not exhibit distinguishing marks of some kind. In the living world there is nothing which comes near to mathematical accuracy, no process characteristic of vitality under the sole dominion of physical and chemical law. In the world of life we have never-ceasing movement. In every tissues in every organism, from the very lowest to the highest and most complex, from the youngest to the oldest, from the first moment of the appearance of living matter long, long ago, to the production of that which began to live just this instant, movement which ceases only with death has existed — movement in matter destitute of structure, containing much water, clear as glass, mobile in all its parts—movement called spontaneous, automatic — movements of matter which may be seen but the exact nature and cause of which is undiscovered. Among the substances obtained after its death are proteids, fatty and certain other organic matters, and salts; but the most important of all, and invariably present in large proportion in everything that lives and absolutely necessary to its life, is water. Without water there is no life. How the materials obtained after the death of bioplasm were arranged, how their elements were grouped in the living state, no chemist has yet been able to decide; nor has any physicist yet discovered what happens to living matter at the moment of its death. In fact, neither the chemical constitution nor the molecular arrangement of the matter that lives—of the bioplasm—has yet been determined.

It seems to be agreed that the living body is to be regarded as a transformer of energy, a converter of force, but the transformation, the conversion, is, I think, effected only in the colourless, structureless, mobile living matter, in the bioplasm which constitutes so small and so inconspicuous a portion of any complex living organism. The bioplasm is the only spot which is the seat of action of the wonderful changing, transforming power which is imparted to the non-living matter just brought in solution within the sphere of its influence where the latter acquires similar powers and then manifests vital movements. But heat and light and electricity are not altogether unknown in connexion with the mobile particles of certain kinds of moist living

Digitized by Google

bioplasm in which movement is always present. The instant living matter dies all vital movement, all transforming action, ceases. Shall I be expelled from all scientific society if I venture to suggest that this wonderful power upon which depends the living and dying of the only matter which lives now and of that which lived in the past is—Vitality?

(To be concluded.)

A CASE OF GASTRO-INTESTINAL HÆMORRHAGE IN A NEWLY-BORN CHILD; TREATMENT BY LARGE DOSES OF CALCIUM CHLORIDE; RECOVERY.

BY L. A. PARRY, M.D., B.S. LOND., F.R.C.S. ENG.,
HONORARY PHYSICIAN TO THE ST. PANCRAS AND NORTHERN DISPENSARY.

THE child who is the subject of this paper was the first offspring of perfectly healthy parents. There was no family history of hæmophilia and the only point of note as regards the labour is that forceps were used when the head was quite low down in the pelvis as there was some delay in the birth. The puerperal period of the mother was quite normal, but it may be noted that her pulse kept well above 100 per minute for the first week, although the temperature never rose above 99·2° F. after the first day. During the first three days of the child's life no unusual symptoms were observed. On the fourth day, however, almost exactly 72 hours after the birth, the infant vomited some dark reddish-brown blood and 3 hours later passed a motion of the same colour, another motion in 2 hours, and another again 2 hours afterwards—i.e., blood was vomited once and three motions of blood were passed during the day, the first being at 12 midday. The amount of blood on each occasion was not great, but it left the patient in a rather anæmic condition. On the next day there was no hæmatemesis. The child was sick once or twice after taking medicine, but there was no blood. Four more motions of blood of about the same amount as the day before were passed and the infant was very anæmic and feeble indeed. On the next day there was no repetition of the hæmatemesis, but there were four more motions of blood considerably less, however, in amount. After this no more blood was passed and the child rapidly convalesced from the resulting anæmia.

The diagnosis of the cause of gastro-intestinal hæmorrhage in newly-born infants is not as a rule difficult. The conditions which may give rise to it are as follows: (*a*) There may be hæmorrhage into the bowel caused by pressure at birth, just as there may be hæmorrhage into other viscera, such as the brain or lungs. It may even be of sufficient amount to cause intestinal obstruction. In my case this explanation was negatived by the fact that the child passed ordinary motions for the first two days of life. This could not have been the case if there were blood in the bowel at birth, for it would certainly have shown itself at the latest at least after one or two motions had been passed. (*b*) There may be acute fatty degeneration of the newly-born. Buhl, in 1861, first described this rare disease, but it is very doubtful whether it is really a definite disease at all. The symptoms are as follows. The child is born in a state of asphyxia without obvious cause. There are cyanosis, blood extravasation under the skin or mucous membrane of the mouth or conjunctiva, jaundice, general œdema, hæmorrhage during the separation of the cord or from the stomach and bowels, and death occurs in two weeks. As all these symptoms except the gastro-intestinal hæmorrhage were absent this was not a case of this disease. (*c*) There may be hæmophilia, but there was no family history of this nor was there any other hæmorrhagic tendency in the child beyond that described—e.g., the cord separated without any bleeding. (*d*) Vomiting and the passage *per rectum* of swallowed blood either from the mother's nipple or from some lesion of the child's mouth or nose may occur, but in this case there was nothing of this kind present. (*e*) There may be ulceration of the duodenum or stomach, as described by Dr. Goodhart and others. In that case hæmatemesis would have been a more pronounced symptom than it was in my case, where it only occurred once. These cases are always fatal. (*f*) Intussusception may occur, but then there would be no hæmorrhage from the stomach and a tumour would be present, and mucus as well as blood would have been found in the stools. (*g*) Congestion of pelvic veins due to a cessation of the circulation in the cord when it was tied might have been another condition, but then the hæmorrhage would have come on directly after birth and would have been accompanied by discharge of blood *per vaginam* from the same cause—i.e., pelvic congestion. Lastly, there may be (*h*) hæmatemesis and melæna neonatorum, and this is the class in which I place this case. The symptoms are simply those which are implied in the name—the passage of blood by the rectum and the vomiting of it in newly-born children. The pathology in this condition is obscure; the necropsy in these cases simply reveals a very much congested condition of the gastro-intestinal mucous membrane without any discoverable cause. Sometimes even this congestion is not seen and no abnormality whatever can be found.

The usual treatment of such cases is by the administration of hæmostatics, such as ergot, perchloride of iron, &c., but the majority prove fatal in spite of all attempted remedies. I gave my patient very frequent 5 gr. doses of calcium chloride. On the first day of the bleeding none was given; on the second day eight doses of 5 gr. were administered every hour through the day and then every two hours through the night; on the third day the same; and on the fourth day every two hours through the day. The drug was then stopped as the bleeding had ceased for twenty-four hours. Altogether the child took 160 grains in three days. The hæmorrhage began to lessen twenty-four hours after its exhibition and ceased completely in forty-eight hours. The resulting anæmia was treated in the usual way by the administration of iron. A practical point to note is this. I warned the mother not to worry if the stools turned black-coloured and it was just as well I did, for she said she would certainly have thought the colour, which was due to the taking of the iron, arose from a recurrence of the bleeding unless she had been prepared. I cannot say whether the stoppage of hæmorrhage was *post* or *propter* the giving of the calcium chloride, but certainly the bleeding ceased soon after its exhibition and I should use it again in a similar case. I have often tried it in other forms of hæmorrhage—e.g., epistaxis, bleeding from tooth socket, &c.—but this is the first case in which I have seen any benefit after its employment.

Bartholomew-road, N.W.

THE SPONTANEOUS OCCURRENCE OF A VESICAL FISTULA IN THE GROIN IN A CASE OF PARAPLEGIA WITH RETENTION OF URINE.

BY JAMES COLLIER, M.D., B.Sc., M.R.C.P. LOND.,
JUNIOR HOUSE PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE, W.C.

THE following case exemplifies a remarkable and exceedingly rare result of prolonged retention of urine with overflow and cystitis. For permission to publish the notes I am indebted to Sir William Gowers.

A man, aged forty-eight years, was admitted into the National Hospital for the Paralysed and Epileptic, under the care of Sir William Gowers, on May 24th, 1898, complaining of partial paralysis of both legs and that his urine ran away from him through a hole in the right groin. His family history was unimportant. His previous health had been good. Some years ago he had an abscess in the jaw and another in the left groin. He had never suffered from lead-poisoning.

In June, 1896, the patient was seized with pain in the right leg like "rheumatics." The leg became weak and he commenced to drag it in walking. At the end of a week he had to give up his work on account of pain and weakness in both legs. He was then taken into Charing-cross Hospital, where the bladder was found to be distended. At the end of a fortnight he had completely lost all power in the right leg and nearly all in the left leg and in either leg he could not feel when he was touched. He lost all control over both

Digitized by Google

sphincters and developed cystitis. Since this time he had had no pain. He remained in hospital for seven months, where the bladder was kept clean with regular catheterisation and irrigation. His condition of paraplegia did not improve in the hospital but the feeling returned in his legs to some extent.

On leaving Charing-cross Hospital the patient returned home and was treated by his own medical attendant. No instrument was passed and for five months the patient's urine constantly dribbled away. He says he could during this time always feel a round swelling (the distended bladder) above the pubes, but he had no pain. The urine was very offensive. At the end of this time (July, 1897) a small hard lump appeared in the right groin; it was tender and in a few days burst, letting out some pus and a good deal of offensive urine. Since this time the whole of the urine had been voided through the opening in the right groin. He had passed nothing *per urethram* except a little pus occasionally. For the last nine months he had been regaining power in the legs and his sensation had improved greatly, but he was still unable to stand.

The present state of the patient is as follows. He is a sparsely-nourished, sallow-faced man. He complains of no pain. His appetite is good and his temperature is normal. The mental state, speech, special senses, optic discs, cranial nerves, upper extremities and trunk muscles are normal. The spine presents no peculiarities. The lower extremities are rigid at all joints and in all positions. Both feet are dropped and there is some contracture of the calf muscles. There is considerable adductor spasm and the legs are frequently drawn up reflexly. He can flex, extend, abduct, and adduct both hips, but slowly and stiffly. He can flex and extend the knees and can flex the ankles and toes. He cannot dorsiflex the ankles. The legs are rather thin and the muscles are small, but there is no localised wasting. He cannot stand or walk. There is slight diminution of tactile sensibility below the knees on either side, but light touches and pricks are felt everywhere. As regards the sphincters, there is reflex incontinence of fæces. No urine is passed *per urethram*. A No. 16 silver catheter can be passed without much difficulty. The prostate is enlarged. The plantar reflexes are exaggerated and equal. The knee-jerks are exaggerated and equal. There is double foot and double rectus clonus. The heart, lungs, and abdominal viscera present no peculiarities. In the right groin, just above and external to the pubic spine, there is a sinus about 3 in. long. The track begins external to the spermatic cord and then passing behind it opens into the front and right lateral aspect of the bladder. The skin for some inches round this sinus is raw and covered with large moist papules. Urine is constantly dribbling from the sinus. About 3 oz. of dark brown very offensive urine were removed from the bladder by the catheter. On careful examination no signs of the presence of a calculus were found. The bladder is small and contracted. When empty not more than 3 oz. of fluid can be made to enter the bladder even under the pressure of 3 ft. of water.

The origin of the fistula was probably a slough of the bladder wall resulting from the long-continued distension and cystitis followed by a peri-vesical abscess confined by progressive conservative processes and extending underneath the peritoneum to the right groin. It seems unlikely that extravasation of urine into the præ-vesical space with the formation of a secondary abscess had occurred, since at no time had he absolute retention of urine and the signs immediately preceding the bursting of the abscess were quite local. The absence of marked pain and discomfort when these processes were going on and when the patient himself distinctly remembers that he could feel touches perfectly well all over the inguinal regions is remarkable. There was probably such blunting of sensibility from the myelitis that although he could feel touches and distinguish a pin point readily he was unable to feel more severe painful impression in a natural degree, a condition which is not infrequently seen in lesions of the spinal cord interfering with sensation.

CARDIFF.—At the meeting of the Cardiff Board of Guardians held on June 18th it was resolved to accept a tender for £2330 for the erection of a new infants' wing at the workhouse.—Dr. S. W. Wheaton, of the Local Government Board, held an inquiry at Cardiff on June 28th into an application of the Cardiff Corporation for sanction to borrow £21,600 for the erection and furnishing of new wards at the borough sanatorium for infectious diseases.

NORTH-EASTERN HOSPITAL FOR CHILDREN.

A CASE OF PORENCEPHALUS SIMULATING A DEPRESSED FRACTURE OF THE SKULL WITH A CEPHALHÆMATOMA; NECROPSY.

(Under the care of Mr. H. P. DEAN.)

FOR the notes of the case we are indebted to Mr. J. H. de Villiers, late house surgeon to the hospital.

The patient was a female child, aged four months. There was nothing of note in the family history and in particular there was no evidence of epilepsy or other forms of nervous trouble. The mother had had five other children, all of whom were healthy, and there had been one miscarriage, after the fourth child. With regard to the previous history, the patient was a full-term child (vertex presentation) and the membranes were ruptured thirty-six hours before birth; no forceps were used. A few days after birth the mother noticed a small depression over the right side of the skull, but, thinking that it was due to pressure, she took no more notice of it. It was said that there had been slight wasting since birth, but otherwise nothing wrong was noticed. There were no convulsions. The child was fed from the breast. On Sept. 21st, at 1 A.M., the mother fell down with the infant in her arms; she was unable to say whether the child's head struck against any object, but immediately afterwards she noticed a large swelling extending over the right side of the head. The child was taken to the hospital within a quarter of an hour of the accident; she was found to be unconscious, pale, and collapsed and was immediately admitted. On further examination the child was found to be a healthy-looking and well-nourished infant. Over the right parietal region a large, tense, fluctuating, but not pulsating, swelling presented, covered by normal scalp, which showed no signs of bruising or discolouration. Immediately in front of the swelling, at the junction of the parietal, frontal, and temporal bones, was a small depression simulating a depressed fracture. Both pupils were active to light, but the right was larger than the left; there was no strabismus, but it was impossible to test the ocular movements. No difference in the two sides of the face was detected. The right arm and leg were rigid and the left appeared to be normal. Nothing definite could be made out about the knee-jerks. The temperature was 98° F. From the symptoms the case was considered to be one of depressed fracture of the skull with a cephalhæmatoma. The following is a copy of the notes of the progress of the case. At 6 A.M. the patient was still unconscious. The temperature was 97·6° F. By 10 A.M. the temperature had risen to 100°; the patient was sick twice and was still unconscious. On the 22nd she was sick twice. At 10 A.M. the temperature was 101·6°; otherwise the condition was unaltered. On the 23rd there were marked irregular twitchings of the right arm and leg and complete paralysis of the left arm and leg; no difference in the two sides of the face was detected. The temperature ranged between 102·4° and 99°. On the 24th the child seemed to be conscious, the pupils were equal, and she took milk fairly well. On the 26th the swelling was less tense, and through the swelling two ridges of bone could be felt running from before backwards about an inch apart. The temperature varied from 103° to 100°. On the 30th the temperature was lower, the child seemed to take more notice of her surroundings, and she took food well. On Oct. 1st, at 2 A.M., the temperature was 101·6° and at 10 A.M. 97·6°; rigidity was more marked on the right side; the left side was unaltered. From this date to the 6th the temperature had only on one occasion reached 100°. The child had vomited twice; she seemed much brighter, but otherwise she was unchanged. The patient was sick once on the 7th and twice on the 8th; her temperature was normal. She

Digitized by Google

was sick once on the 10th and twice on the 12th, the temperature varying between 97·4° and 98°; otherwise her condition was unaltered. From the 12th to the 22nd there was nothing of note; if anything the rigidity seemed to be less marked; there was no vomiting. The temperature on the latter date was normal. On the 23rd and 24th some diarrhœa occurred, which improved under treatment. On the 25th the temperature was normal. On the 29th, as the child's local condition remained unaltered, Mr. H. Percy Dean made an exploratory incision under chloroform. Immediately on making the skin incision a quantity of cerebro-spinal fluid gushed out. Over an area of about the size of a florin the covering of the cavity inside the brain was extremely thin and at one spot was adherent to the scalp. The margin of the aperture thus made was ragged and seemed to be composed of very degenerated grey cortex. When the flap was completely turned down it was noticed that the right parietal bone was divided into two almost equal halves by a fissure nearly an inch in breadth running from its anterior to its posterior margin and ending anteriorly in the depression before noticed. Beneath the fissure could be seen a smooth-walled cavity evidently in the brain substance; on the floor of this cavity was noticed an opening of sufficient size to admit the little finger, and on passing a probe through the opening it was found to enter the right lateral ventricle. The case was considered to be one of porencephalus, so the skin incision was closed with silkworm gut and dressed with cyanide gauze. The temperature at 2 P.M. (before the operation) was 98°; at 6 P.M. it had risen to 101·4°. On the 30th the general condition was worse. The temperature at 2 A.M. was 100·6° and by 2 P.M. it had risen to 104·6°. The cerebro-spinal fluid was gradually draining away. The patient was sick four times. On the 31st the temperature at 2 A.M. was 100·4°, at 6 P.M. it was 102·4°. Cerebro-spinal fluid was still draining away. The patient was sick four times. On Nov. 1st her general condition was much worse. The temperature at 6 A.M. was 102·2° and the child died at 3 P.M. The temperature just before death was 100·8°; otherwise there was nothing of note.

Necropsy.—A post-mortem examination of the head only was allowed. A widely gaping fissure, running from the anterior to the posterior border, divided the right parietal bone into upper and lower parts of almost equal size. The fissure was closed in its anterior and in its posterior third by united dura mater and periosteum, but the middle third was open, the opening being 2 in. by ¾ in. wide. At the margin of the opening brain matter, membrane, and periosteum were fused together and in a thin layer. Beneath the dura mater, in the upper margin of the opening there were the remains of an old hæmorrhage. Only a thin layer of tissue, evidently the thickened ependyma, prevented the greatly dilated descending horn of the right lateral ventricle from opening at the fissure in the parietal bone. There was no sign of inflammation in the wall of the cavity—in fact, no evidence of septic infection of any kind in the brain or on its surface could be detected. The first frontal convolution, the upper two-fifths of the ascending frontal and ascending parietal, the superior parietal and occipital convolutions were present on the right side. The mesial aspect of the right hemisphere showed a normal arrangement and development of convolutions and fissures. The lower three-fifths of the ascending frontal and parietal convolutions were absent, so were the angular supra-marginal gyri and the part of the posterior parietal adjacent to the angular gyrus; all these convolutions with the first temporo-sphenoidal were involved in the mixed mass of tissue which surrounded and bound the opening in the parietal bone. The second and third temporo-sphenoidal convolutions were long, small ridges, crushed together towards the cerebellar aspect of the temporo-sphenoidal lobe. On the left side the third frontal convolution was well developed, but on the right, although an anterior limb of the fissure of Sylvius was distinctly present, it was impossible to distinguish a distinct third or second frontal convolution, both being represented by a narrow mass of fine convolutions. The island of Reil on the right side was half the size of that on the left; its central sulcus was merely indicated, it had two slight convolutions in front of the central fissure and only one behind it; the island was exposed, the operculum being so slightly developed.

Remarks by Mr. DE VILLIERS.—I have endeavoured to describe this case clinically, not pathologically, especially as no examination of the cord was allowed. Writers on the subject have expressed very diverse views as to its nature. Anyone interested in the subject will find references to other published cases and papers in the following:—Kundrat: Die Porencephalie: eine Anatomische Studie, Gray, 1882; Audry: Les Porencéphalies, *Revue de Médecine*, June and July, 1888; and Norman and Fraser: A case of Porencephaly, *Journal of Mental Science*, October, 1894. By the kind permission of Mr. Dean I am allowed to publish this case.

Remarks by Mr. DEAN.—When the child was seen by me for the first time about three days after admission the symptoms of collapse had subsided and I regarded the condition as one of gradual recovery from a severe contusion and probable laceration of the brain together with either a cephalhæmatoma or traumatic meningocele (meningocele falsa). There were no symptoms of compression of the brain, and as the child seemed to be distinctly improving I decided not to operate at once but to wait a few days before exploring the swelling. At the operation, as soon as the flap of scalp was reflected, the condition was obviously a long-standing one. The only evidence of any recent mischief was the small blood-cyst found at the upper part of the wound. Possibly this was the result of the recent accident, but on the whole I was inclined to think that it was considerably older than this. On enlarging the accidental tear in the thinned-out cerebral cortex a huge cavity was found which I have no doubt belonged to the group known as porencephalus. Using this term in its widest application it may be said to include two distinct conditions: (1) a mal-development of the brain at a fairly early stage of embryonic life; and (2) some extensive lesion, probably vascular in origin, during the later stages of intra-uterine life or at or after birth. This last condition is sometimes called pseudo-porencephalus. In deciding to which group any case belongs there are the following points to consider:—1. Whether the cavity communicates with the lateral ventricle. As a rule in pseudo-porencephalus there is no communication, whereas in congenital porencephalus there is always a communication, usually of about the size which would admit the little finger as in this particular case. Occasionally, in pseudo-porencephalus there is a communication due to an unusually extensive destructive lesion and in such cases the communicating aperture is much larger than in the true cases. 2. In pseudo-porencephalus the cerebral convolutions around the margin of the cavity are quite irregular in distribution, such as one would expect from an extensive hæmorrhage. In true porencephalus the convolutions though malformed are fairly regular in shape and distribution. 3. In true porencephalus the thin layer covering the cavity on its superficial aspect is composed of imperfectly developed brain tissue, whereas in pseudo-porencephalus the lining membrane and the superficial covering are composed of organised tissue containing little or no evidence of its nervous origin. On the whole, therefore, it is fairly clear that this case belongs to the group of true porencephalus and that death was due to alteration in the vascular mechanism of the brain produced by the draining away of cerebro-spinal fluid and to other conditions.

ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE.

A CASE OF TRANSPERITONEAL LIGATURE OF THE EXTERNAL ILIAC ARTERY FOR ANEURYSM OF THE COMMON FEMORAL; CURE.

(Under the care of Mr. FREDERICK PAGE.)

ALTHOUGH, as Mr. Page mentions in his remarks, many of the text-books on operative surgery do not describe transperitoneal ligature of the external iliac, yet the subject has not by any means been entirely neglected. A very good account of the operation is given by Mr. Jacobson[1] and by Mr. Treves.[2] Mr. Page refers to Mr. Makins's case in 1892, but he may be interested to know that in the same patient subsequently a similar aneurysm appeared on the other side of the body, and, further, Mr. Makins tied in 1893 the other external iliac, so that in this case both external iliacs were tied with success. Mr. Jessop's case was mentioned in a paper read before the Leeds and West Riding Medico-Chirurgical Society on Nov. 2nd, 1894, and it was reported in THE LANCET of Nov. 17th, 1894, p. 1142. The

Digitized by Google

question of transperitoneal or extra-peritoneal operation for the ligature of all the iliac arteries is practically the same, though the arguments in favour of the transperitoneal method are especially strong in the case of the common and the internal iliacs, and it has been urged[3] that the ordinary operation for ligature of the external iliac is so simple that it is undesirable to employ the transperitoneal method for this vessel. Mr. Page's case is of great value, as it shows how simple is the transperitoneal operation, and it is very probable that this method will be more commonly employed in the future. It requires care that the wound is kept aseptic, but that is equally true of the extra-peritoneal method, for if suppuration should appear outside a peritoneum which has been stripped up sloughing is not unlikely to ensue. As to the material of the ligature we cannot see why any harm should arise from aseptic silk.

A man, aged forty-seven years, was, on March 10th, 1898, admitted to the Royal Infirmary, Newcastle-upon-Tyne, under the care of Mr. Frederick Page, suffering from aneurysm of the left common femoral artery of three months' duration. The patient complained of pain and stiffness in his left groin and of pain on the inner aspect of his knee and said that he was unable to use his left leg. There was an aneurysm of the common femoral as large as an orange. Nine years ago he suffered from rheumatic fever. He had now "a very soft aortic systolic and a mitral regurgitant murmur." He had led an irregular life, but had never had syphilis. On March 17th the abdomen was opened by an incision 3 in. long, commencing 1 in. above Poupart's ligament, parallel to and just outside the sheath of the rectus. The intestines and omentum were then packed off by means of sponges and free access was obtained to the vessel, round which a catgut ligature was readily passed and tightly tied. Pulsation in the aneurysm at once ceased. The abdominal wound was closed in layers, the limb was wrapped in cotton wool, and the patient was removed to bed. No constitutional disturbance followed the operation and the wound healed by first intention. On the 19th pulsation returned in the aneurysm, but it was much diminished on the 20th and wholly absent on the 21st, since which date there has been no return. The patient left the infirmary on April 12th cured and is now quite well.

Remarks by Mr. PAGE.—On Sept. 20th, 1892, Mr. Makins at St. Thomas's Hospital and Mr. Mitchell Banks at the Royal Infirmary, Liverpool, in two patients suffering from aneurysm of the common femoral tied the external iliac artery through the peritoneum and both cases were cured. Since then the vessel has been twice, at least, tied by the same method, once by Mr. Brown at Leeds in 1893, and once by Mr. Coppinger of Dublin in 1894, for aneurysm of the common femoral. In Mr. Brown's patient, a fat subject, there were two aneurysms, gangrene followed, and the patient died after amputation. Mr. Coppinger's patient was cured, so that with mine, 5 cases have been recorded as operated upon by this method and 4 of them have been successful. I understand that Mr. Brown of Leeds tied the vessel a second time by the same method last year. Mr. Jessop of Leeds has also once done so, but I have not been able to find reports of these two cases. I notice that most of the text-books on operative surgery do not describe transperitoneal ligature of the external iliac. In the last edition of Erichsen it is stated that "the surgeon may resort to ligature of the vessel through the peritoneum in those cases in which Astley Cooper's operation is impracticable." Mr. T. Holmes, who advocates pressure before ligation of the external iliac where practicable, says that wound of the peritoneum "is not necessarily attended with fatal or even with serious consequences; in fact, a successful case was lately published in which the peritoneum had been divided by mistake for the transversalis fascia to the extent of the external wound, but any injury to the peritoneum should nevertheless be most carefully avoided." I take it, therefore, the general surgical opinion still is that extra-peritoneal ligation of the external iliac is the operation which should be selected, the trans-peritoneal method only being resorted to where extra-peritoneal ligation is impracticable. My own experience is far too limited to allow me to express an opinion on the relative merits of the two procedures. I have tied the external iliac twice for aneurysm of the common femoral, once by the extra-peritoneal and once by the transperitoneal method. Both cases did well. Should I ever have occasion, however, to tie the external iliac again for an aneurysm of the common femoral I should certainly, without any hesitation, select the transperitoneal operation, tying the vessel tightly with a catgut ligature. Mr. Makins, Mr. Brown, and Mr. Coppinger all tied the vessel tightly with a silk ligature. Mr. Mitchell Banks used a catgut ligature and did not tie it tightly. Eleven days after operation his patient became suddenly alarmingly ill from what seems to have been embolism, but she recovered. I am rather surprised to find that no inconvenience arose from the use of the silk ligatures. I should expect that silk would be more liable to give rise to subsequent trouble than catgut. What is the best ligature and what is the best method of its application to an artery in continuity are points, among many others, in the treatment of aneurysm which it would be most interesting and instructive to hear debated by surgeons who have had considerable practical experience in this department of surgery. Much has happened since 1870 when the late Dr. G. Y. Heath, in his address on Surgery at the meeting of the British Medical Association in Newcastle-upon-Tyne, contrasted the relative merits of pressure and the ligature in the treatment of aneurysm in the following terms: "I should rather leave to those who best know what dangers encompass him who is submitted to the knife and the ligature—the shock, the suppuration, the erysipelas, the pyæmia, the gangrene, and the secondary hæmorrhage—the appraisement of a measure which after a few hours' sleep leaves the awakened patient free from his disease, with no wound to heal, no further risk to run, and to say whether any surgical proceeding ever more truly deserved the application of the old maxim, *Cito, tute et jucunde.*"

[3] Mr. Clement Lucas, Brit. Med. Jour., Nov. 5th, 1892, p 1033.

Medical Societies.

OBSTETRICAL SOCIETY OF LONDON.

The Sagittal Fontanelle.—Fronto-anterior Positions of the Head.—Acute Bedsore following Parturition.—Exhibition of Specimens.

A MEETING of this society was held on July 6th, Dr. C. J. CULLINGWORTH, President, being in the chair.

Dr. ARNOLD LEA read a paper on the Sagittal Fontanelle in the Heads of Children at Birth. He stated that abnormal fontanelles had been known to be present in the head of the fœtus at birth for many years; several of these membranous spaces had been described (naso-frontal, cerebellar, medio-frontal, sagittal), of which the most interesting to obstetricians was the sagittal fontanelle, first described by Gerdy in 1837. Dr. Lea's observations were based upon the examination of 500 consecutive cases at birth. The sagittal fontanelle was situated 2 cm. in front of the posterior fontanelle on a transverse line drawn between the two parietal eminences. Its average length was 1½ cm. and width 1 cm. It might form a space as large as the anterior fontanelle or it might be developed on one side only. The edges of the membranous space were usually formed of well-developed bone, but at times there was deficient ossification of the posterior part of the parietal bone. He had found the membranous space present in 4·4 per cent. of his cases; he had not included those in which there was only a notch in the parietal bone. The fontanelle was bilateral in 17 cases and unilateral in 5 cases; in 4 instances it extended up to the parietal eminence on each side. A description was given of the development of the parietal bones and of the obstetric and medico-legal interest of the fontanelle and of its effect in facilitating moulding of the head.—Dr. HERMAN said that two practical points arose out of the laborious and careful investigation of Dr. Lea. The first was that a sagittal fontanelle might mislead one who diagnosed the fœtal position by feeling the sutures and fontanelles. But this would not trouble anyone who was accustomed to diagnose the position by abdominal palpation. The second was that a sagittal fontanelle indicating backward ossification might invite a trial with forceps in a case which with a very hard head would call for perforation.—Dr. HERBERT SPENCER expressed surprise that the fontanelle had been found in 4·4 per cent. of cases. He asked Dr. Lea whether his observations were clinical or post-mortem. He (Dr. Spencer) was well acquainted with fissures in the parietal

Digitized by Google

bone which were common and every obstetrician knew how depressible the upper edge of the parietal bone often was; what was really only a fissure might therefore appear to the examining finger as a space; but having carefully examined the skulls of over 300 new-born infants post mortem he had not met with one instance of a sagittal fontanelle at all comparable to the anterior fontanelle. He had, however, met with parietal fenestra and with insular ossification and absence of ossification in the parietal bones of the mature fœtus. He had no doubt that as a considerable anatomical space the sagittal fontanelle occurred with much greater rarity than that stated by Dr. Lea.—The PRESIDENT said it would no doubt have been quite as much a surprise to the Fellows generally as it had been to him to learn that a genuine sagittal fontanelle had been found in so large a proportion of cases. He thought that the liability of this extra fontanelle to be mistaken for a fracture the result of violence had an important medico-legal bearing.—Dr. LEA, in reply, stated that the percentage of cases of parietal fontanelle observed by him was similar to that of M. Hemy. In children some months old instances in which it remained open were not uncommon. He had examined two cases in which the infants died soon after delivery.

Dr. GEORGE ROPER read a note on some Difficult Cases of Fronto-anterior Positions of the Fœtal Head. He stated that after an extensive experience in difficult labours he never felt satisfied with the knowledge he had of the difficulties connected with the fronto-anterior positions of the fœtal head in labour. With a child beyond average size or with a small or misshapen pelvis considerable difficulties occurred. He referred to the description of the labour in Dr. Herman's book on Difficult Labour and stated his opinion that the difficulty was due to the position of the child's trunk. He (Dr. Roper) recommended after a moderate trial with forceps podalic version in the treatment of these cases and showed an instrument he had devised for facilitating traction on the leg.—Dr. HERMAN thought that Dr. Roper had done service in calling attention to the fact that the mechanism of delivery did not depend only upon the relation of the head to the pelvis. The position of the trunk caused extension of the spine, which led to extension of the head. Also, as Dr. Roper had pointed out, the fœtus would enter the pelvis more easily when its concave abdominal aspect was applied to the mother's lumbo-sacral convexity.—Dr. HORROCKS said that he agreed that the tendency in these cases was at first towards extension, but after further descent into the pelvis the head tended to be flexed by the uterine forces. The treatment depended upon the mobility of the fœtus: when there was little or no mobility the proper treatment was not rotation or version but craniotomy.

Dr. BLACKER read a communication on a case of Acute Bedsore following Parturition.

The following specimens were shown:—

Dr. PEMBREY: Five Cake-like Bodies (containing fœtuses) which were found free in the Peritoneal Cavity of a Large Rabbit.

Dr. J. D. MCCAW: A Cystic Fibro-myoma of the Uterus removed by Laparotomy from the Uterus in the Middle of Pregnancy; delivery at term.

Dr. WISE: Ovum with Hæmorrhage into the Placenta.

Dr. TATE: Uterus removed by Vaginal Hysterectomy.

Dr. HERBERT SPENCER: Ovarian Dermoid which, Incarcerated in the Pelvis, was pushed up in the Middle of Pregnancy and Removed after Delivery at Term.

OPHTHALMOLOGICAL SOCIETY.

Subconjunctival Blood-letting for Hæmorrhagic Retinitis.—The Mechanism of the Conjugate Movements of the Eyeballs.—Large Clear Cyst of the Conjunctiva.—Chancre of the Lacrymal Sac.—Exhibition of Specimens.

A MEETING of this society was held on July 8th, Mr. H. R. SWANZY, President, being in the chair.

Mr. RICHARDSON CROSS read a paper on Subconjunctival Blood-letting for Hæmorrhagic Retinitis. Recognising the fact that a considerable amount of blood escaped from the wounded vessels in squint and other subconjunctival operations without any ill-effect Mr. Cross determined to try the effect upon intraocular hæmorrhage or congestion of a more or less free division of the blood-vessels running along the muscles and in the subconjunctival tissue. For this purpose he made free incisions beneath the conjunctiva either between the inferior and internal recti or between the superior and external recti; the incisions were followed by the use of hot fomentations. From the result of this kind of interference in several cases Mr. Cross felt justified in recommending this plan of abstracting blood from the branches of the ophthalmic artery. In one case in which there were numerous retinal hæmorrhages round the disc, with much congestion of the retinal vessels and some optic neuritis, leeches and general medical treatment had been applied without benefit and vision was reduced to $\frac{5}{60}$. Free incisions were made into the subconjunctival tissue with strabismus scissors so as to lacerate as many vessels as possible and warm fomentations were afterwards applied. The next day the pupil was dilated and there was marked diminution in the swelling of the disc, with an improvement in vision. This improvement was steadily maintained and the vision was eventually completely restored. Several other cases were quoted in which considerable improvement resulted.

Dr. ALDREN TURNER read a paper on the Mechanism of the Conjugate Movements of the Eyeballs. He showed that there was accumulating evidence in favour of the sixth nerve nucleus being the lower or pontine centre for the associated action of the internal and external recti muscles and that the fibres from the sixth nucleus of one side probably passed directly into the third nerve of the opposite side, without the intervention of cells in the third nucleus, facts which indicated that the internal recti were doubly innervated—on the one hand from the third nucleus for convergence and on the other from the sixth nucleus for lateral movement. Respecting the path by which impressions were conveyed from the cerebral cortex to the sixth nucleus he referred to an experiment in which the tegment of the pons was divided without interference with the sixth nucleus. As a result conjugate deviation of both eyes to the opposite side, with inability to move them to the side of the lesion, was observed. The conclusion drawn from this observation was that the cortico-pontine fibres decussated in the neighbourhood of the quadrigeminal bodies and passed downwards in the tegment of the pons to the sixth nucleus.—The PRESIDENT made some observations on the position of the nuclear centre for convergence and on the probability of there being not one but several cortical centres for conjugate movements of the eyes.—Mr. JESSOP thought that absence of convergence was a very rare condition; he knew of only one case in a boy subject to epileptic fits. He had advanced both internal recti with the result that the boy now had several metre angles of positive convergent power.—In reply Dr. TURNER stated that he had only seen one case of paralysis of convergence, while the conjugate movements were unaffected. He referred to the loss of pupillary contraction on attempts at convergence in that case, while the pupillary light reflex was retained. This phenomenon was the converse of the Argyll-Robertson pupil.

Mr. SIMEON SNELL (Sheffield) related particulars of a case of Large Clear Cyst of the Conjunctiva. The cyst was as large as a hazel nut; it was concealed almost entirely by the lower eyelid, but when the lid was drawn down it bulged forward. The patient was twenty-three years of age; the cyst had been noticed since childhood but was then quite small. Ten months before coming under observation he was struck over the cyst, which enlarged and became bluish in colour; before this it was transparent. Microscopical examination of the cyst, made by Mr. Treacher Collins, showed it to be lined throughout by a single layer of endothelial cells, outside which was some moderately dense fibrous tissue with patches of round-celled infiltration in it. The cyst was probably lymphatic in origin.

Mr. SIMEON SNELL also related a case of Chancre of the Lacrymal Sac. The patient sought advice for what he deemed subacute inflammation of the lacrymal sac. When seen there was no ulceration of the sac, but there was a more than usually defined margin to the swelling. There was nothing to suggest a primary lesion. Later the canaliculus was slit up and the duct probed with some slight relief; afterwards a macular syphilide appeared on the chest and arms with ulceration of the tonsils. Presuming the lesion of the lacrymal sac to be a primary sore the secondary symptoms appeared in correct sequence as to time, the first swelling of the sac being noticed on April 3rd and the rash appeared on May 13th. The thickening of the sac and the rash quickly dispersed under mercurial treatment.

The following living and card specimens were shown :—

Mr. RICHARDSON CROSS : Plastic Operation for Contracted Socket.

Mr. ERNEST CLARKE : Pigmented Mole of the Face and Eyelids.

Mr. ADAMS FROST : Case of Pseudo-glioma.

Mr. MARCUS GUNN : Preparation of a Sclerosed Retinal Artery.

The following are the officers and council of the society who were elected to serve for the session 1898–99 :—President : Mr. H. R. Swanzy. Vice-Presidents : Sir W. R. Gowers, F.R.S., Dr. D. Argyll Robertson (Edinburgh), Mr. R. Marcus Gunn, Mr. R. Williams (Liverpool), Mr. E. Nettleship, Mr. Henry Eales (Birmingham), *Dr. W. A. Brailey, *Mr. Priestley Smith (Birmingham), *Mr. F. Richardson Cross (Clifton), and *Mr. George Cowell. Treasurer : *Dr. John Abercrombie. Secretaries : Dr. James Taylor and *Mr. E. Treacher Collins. Librarian : Mr. W. Adams Frost. Other members of council : Dr. Arthur P. L. Wells, Dr. L. H. Tosswill (Exeter), Dr. C. E. Glascott (Manchester), Dr. Arthur W. Sandford (Cork), Mr. Charles J. Oldham (Brighton), Dr. Howard H. Tooth, Dr. W. A. Turner, Dr. G. E. Wherry (Cambridge), Dr. S. H. Habershon, *Mr. J. B. Lawford, *Mr. W. J. Cant (Lincoln), and *Mr. Sydney Stephenson. The gentlemen whose names are marked with an asterisk were not on the council, or did not hold the same office, during the preceding year.

Reviews and Notices of Books.

A System of Medicine. By Many Writers. Edited by THOMAS CLIFFORD ALLBUTT, M.A., M.D. Cantab., LL.D. Glasg., F.R.S., F.R.C.P. Lond., &c. Vol. V., Diseases of the Respiratory and Circulatory Systems. London : Macmillan and Co. 1898. Price 25*s.* net.

THE appearance of another volume of this notable work will be welcomed by many a practitioner and student. A striking feature is the large number of contributors which the editor has secured ; several fresh names appear in the present volume which completes the Diseases of the Respiratory System and embarks on those of the Circulatory System. Needless to say that the work continues to maintain the high level of excellence of the previous volumes. Dr. W. Ewart opens with an article on Bronchitis which is admirably arranged and clearly expounded. We note his reference to the frequent association of bronchitis with pleurisy and his statement that this "pleuro-bronchitis" is often of rheumatic origin. In speaking of plastic bronchitis—an affection of such rarity as to be regarded as almost one of the curiosities of pathology—Dr. Ewart is unable to give much encouragement in the use of solvent treatment of the false membrane. There is a section on Putrid Bronchitis—another affection of some pathological obscurity. The treatment of bronchitis is discussed at some length, being followed by judicious remarks upon prophylaxis. The article on Bronchiectasis is from the same pen and is especially interesting from the breadth of view taken on the subject. Attention is drawn to the recently described condition of "acute bronchiectasis in children," or, as Dr. Ewart terms it, "bronchiolectasis," the illustrations of the condition published by Dr. Sharkey being reproduced. The etiology of bronchiectasis is amply discussed, the author stating views at which he has himself arrived which afford a rational explanation of its occurrence. The signs, symptoms, associated conditions, and the differential diagnosis are well described, but perhaps the most noteworthy feature of the article is the opinion expressed that the treatment of bronchiectasis has of late entered on a new era in the introduction of garlic as an internal remedy by Dr. Vivian Poore, the employment of intratracheal injections and the systematic inhalation of creasote as proposed and carried out by Dr. Chaplin. Surgical treatment by incision and drainage is regarded as a closed chapter in the history of pulmonary therapeutics. The important subject of Pneumonia is dealt with by Dr. Pye-Smith in an article the value of which is enhanced by an appended analysis of 434 cases of the disease from the records of Guy's Hospital and other sources. Dr. Pye-Smith departs, and we think wisely, from the routine order of descriptions of diseases in discussing the clinical features of the disease before entering on its pathology and etiology. He gives a sufficiently detailed account of the present state of knowledge of its bacteriology, and we note that he thinks that there is sufficient evidence for continuing to accept the common belief in the agency of cold in the production of the affection. The historical sketch he gives of the treatment of pneumonia is very interesting. Dr. Pye-Smith also writes upon Catarrhal Pneumonia and Chronic Pneumonia, or pulmonary cirrhosis, which he does not think ever arises directly from lobar pneumonia (p. 49). We miss any separate article upon gangrene of the lung, although, of course, reference is made to this sequel of acute pneumonia in the description of that disease. Dr. Percy Kidd writes upon Phthisis Pulmonalis. In his discussion of the causes of this prevalent malady he shows clearly that the undoubted and progressing diminution in its mortality is to be ascribed in great measure to improved conditions of dwelling rather than to states of soil. This section of his article is very well planned. We would especially mention his treatment of the vexed question of heredity, which has assumed a new aspect since the recognition of the infectivity of tuberculosis has become universal. His summary on the matter, that "the only conclusion at present warranted is that direct inheritance is of decidedly subordinate importance to extra-uterine infection, however acquired," will be assented to by all who have studied the subject. He next describes the pathological anatomy of the disease and divides his consideration of the symptoms under the heads of (*a*) *Acute*, comprising the lobar-pneumonic form, the broncho-pneumonic form, and acute miliary tuberculosis ; and (*b*) *Chronic* pulmonary tuberculosis. Five modes of invasion of chronic phthisis are discriminated—namely, the insidious, the bronchitic, the pleuritic, the hæmoptoic, and the laryngeal. The symptoms and physical signs are admirably sketched and there is a very full account of the various complicating conditions. Under treatment a first place is given to preventive measures and indeed the whole article is a model one. To Dr. Arlidge has been assigned the subject of Pneumoconiosis, a field in which he is an acknowledged authority. At the same time we doubt if sufficient stress is laid upon the frequency with which tuberculous invasion is responsible for the destructive lesions of "dust-phthisis." Of the gravity of the inhalation of dust as a factor in the production of disintegration of the lung none can be ignorant, but yet it may well be that the changes which it initiates render the lungs vulnerable to the attacks of the tubercle bacillus. Dr. Rolleston contributes a description of Pulmonary Aspergillosis in an article which will probably rank as the standard account of a rare condition. Dr. J. Kingston Fowler writes upon Emphysema of the Lungs and also on Syphilitic Disease of the Lungs. Both articles are very careful productions, the latter especially, introducing many new facts of great importance in diagnosis and treatment. Readers of Dr. Fowler and Mr. Godlee's recent work will know what to expect in these contributions, which are characterised by thoroughness and accuracy. The contrast drawn between the lesions of pulmonary syphilis and pulmonary tuberculosis on pp. 328 and 329 is of great value and we venture to quote these instructive passages :—

"1. Tubercle usually affects the apex of the lung and subsequently the apex of the lower lobe ; it tends to progress along a certain route. The primary lesion of syphilis is often about the root and central part of the lung ; the disease

Digitized by Google

follows no definite line of march and gummata may be found in any position. 2. Both tubercles and gummata may undergo either necrosis and caseation or fibrous transformation; but with caseous tubercle the tendency is towards softening and cavity formation is the rule, whereas a caseous gumma very rarely breaks down. 3. The progressive destruction of the lung by a process of disintegration leading to a gradual increase in the size of a cavity, a change so commonly observed in tuberculous disease, is rarely if ever observed in syphilis except as a secondary result of stenosis of one of the main bronchi. 4. In nearly all cases of advanced destruction of the lung occurring in the subjects of syphilis stenosis either of the trachea or of one of the main bronchi is present, whereas this lesion is very rare indeed in tuberculosis. 5. The cavities found in cases of pulmonary syphilis are usually bronchiectatic, but not invariably so, whereas in tuberculosis they are commonly due to progressive destruction of the lung, but may be bronchiectatic. 6. The tendency to the formation of pulmonary aneurysms, which is so marked a feature in tuberculosis, is rarely observed in pulmonary syphilis. 7. Pulmonary lesions in tuberculosis are very common, whereas in syphilis they are extremely rare."

The close association between hay fever and asthma is well recognised in the article treating of these conditions contributed by Dr. Goodhart, who points out how scanty are the data derived from the study of the clinical and pathological history of asthma to explain its phenomena. He discusses the various views advanced as to its pathogeny in an impartial spirit and does not hesitate to point out the difficulties in the way of accepting any one of them as all sufficient. He inclines, however, to the generally accepted explanation of bronchial spasm, together with that of turgescence of the mucous membrane—a combination of the two most advocated doctrines, which probably brings us nearest to the truth, besides connecting the asthmatic paroxysm with the paroxysmal sneezing of hay fever. At any rate the place of these affections in the nosology is on all grounds rather with the neuroses than with affections of the respiratory system.

The section devoted to the Diseases of the Pleura is introduced by an article on Intra-pleural Tension by Dr. S. West. The subject is a difficult one, involving physical problems of some intricacy, and in spite of the attention which it has from time to time received there is still room for its complete investigation. The essay here contributed by Dr. West deserves careful study and propounds the problem in a clear and concise manner. Dr. Gee writes on the subject of Pleurisy, the section on Morbid Anatomy being furnished by Dr. Herringham. In respect to this disease it is interesting to observe how completely the doctrine of its dependence upon specific morbid poisons has come to be accepted, Dr. Gee admitting that even in cases where traumatism and exposure to cold are followed by pleurisy these agencies serve only to facilitate the invasion of specific microbes. It is needless to say that the subject is treated in a most attractive and masterly manner. Professor Finlay writes on Pneumothorax in a practical and instructive manner, his directions as to the indications for paracentesis being sound and judicious.

The conditions and diseases in which the blood is primarily concerned form the subjects of numerous articles under the heading of Diseases of the Circulatory System. They are preceded by an article, entitled "General Features of the Blood," contributed by Professor Michael Foster, and a fairly exhaustive account of the Clinical Examination of the Blood, by Dr. Monckton Copeman, as well as one on Cardiac Physics by Professor Sherrington. Space forbids our attempting to do more than name these valuable additions to a medical treatise, but their inclusion suffices to show how intimately the methods and results of physiology are bound up with the problems of disease. Professor Clifford Allbutt writes upon Chlorosis in a most interesting article which leaves nothing untouched and combines the rich fruits of his personal experiences with a wide knowledge and appreciation of the scientific labours of others, notably amongst recent writings those of Stockman and Lloyd Jones. Dr. Coupland gives a summary account of Pernicious Anæmia, from which it is apparent that by no means the last word has been said upon the pathology or treatment of this remarkable affection; and Dr. S. West writes on Splenic Anæmia, excluding from his consideration the comparatively large series of cases in children to which attention was, we think, first directed by von Jaksch. Nor does he sympathise with the teachings of Banti upon the propriety of early removal of the spleen as a curative measure. For the subject of Hæmophilia the editor has secured the services of Dr. Wickham Legg whose monograph still remains practically the sole English treatise on the subject. It is noteworthy that he speaks very cautiously on the alleged influence of chloride of calcium in arresting the hæmorrhagic tendency. Dr. John Thomson writes on Hæmorrhages in New-born Children, grouping the conditions under the two heads of (1) Traumatic or Accidental Hæmorrhages, and (2) Spontaneous Hæmorrhages, of which the most remarkable are those rare cases of idiopathic nature the etiology of which is much debated, but considered by some to be due to the intervention of micro-organisms. Dr. Stephen Mackenzie discusses the various conditions which have been styled "Purpura" and shows how complex these are, an instructive analysis of 200 cases at the London Hospital bearing this out, besides proving the relative rarity of the condition. Mr. Johnson Smith writes on Scurvy and Dr. Cheadle on Infantile Scurvy, citing his experience as to the much greater incidence of this affection amongst the children of the well-to-do than amongst the children of the poor. Dr. Monckton Copeman contributes an article upon Hæmoglobinuria which, as he says, is probably invariably due to the separation of hæmoglobin from the red corpuscles in the general circulation. He describes three forms, the infantile, the toxic, and the paroxysmal. With respect to the last named it would have been of interest to learn the ultimate fate of the subjects of it. No doubt in many instances the liability to attack lessens as age advances, but there must be cases where local or general diseases have supervened and the association between them and the blood state may possibly throw light upon the pathology of the latter. Dr. Robert Muir is the author of the article on Leucocythæmia, a subject to which he has himself contributed many important facts. His testimony to the value of arsenic "as the only drug which seems to have a distinct effect on the leucocythæmic condition" will be generally endorsed. A valuable pathological study of Dropsy from the pen of Dr. W. H. Dickinson completes the division of the work treating of the blood.

Next comes the section upon Heart Diseases. It opens with an article by Dr. Laurence Humphry upon Congenital Malformation of the Heart, treated in a thoroughly systematic manner which renders it well suited for reference. Dr. Frederick Roberts writes upon Diseases of the Pericardium. His article is most exhaustive, a fitting successor to the elaborate contribution on the same subject to Reynolds's System by the late Dr. Sibson whose painstaking observations are often referred to by Dr. Roberts. Professor Clifford Allbutt writes in his charming style upon Functional Disorders of the Heart, his article abounding in examples from his personal experiences, most happily chosen, whilst throughout the tone is one of hopefulness and good sense. He also writes upon Mechanical Strain of the Heart, a subject which we are glad to see receive such extended notice. A "sign of the times" is the inclusion here of an article upon Injuries by Electric Currents of High Pressure. It is written by Dr. Thomas Oliver, whose conclusion is that the cause of death in such cases is cardiac, probably, as explained by Bleile, from

Digitized by Google

arterial constriction giving rise to an amount of mechanical impediment which the heart cannot overcome. This is contrary to the view of D'Arsonval, who attributes the fatal event to asphyxia. To our thinking Dr. Oliver does not lay stress enough upon the fact that it is not voltage that kills so much as ampèrage—i.e., quantity of current. The voltage of even a small Leyden jar is probably very high—possibly 10,000 volts or so—but the quantity of current being infinitesimal the shock, though unpleasant, does not kill. Dr. Dreschfeld writes upon Endocarditis and Sir R. Douglas Powell upon Diseases of the Myocardium in articles which may well claim to be authoritative. The editor also contributes to the volume a very thorough study of Disease of the Aortic Area of the Heart and Dr. Sansom writes upon Diseases of the Mitral Valve. We trust that enough has been said here to show that the reader of this volume will greatly profit by its perusal. The articles are of high quality and their writers are well chosen, their very number ensuring a delightful variety in style and mode of thought which constitutes a pleasing feature of such treatises. We may also venture to congratulate the accomplished editor upon the near approach of the completion of his labours in the production of a work of abiding interest and value.

Can it be True? A Psychological Study. By G. YEATES HUNTER, I.M.D. London: Digby Long and Co. 1898. Price 6*s*.

"THE principle of heredity is an immense and ever-increasing factor in the human life as the ages roll on." This, one of the closing sentences in Surgeon-Major G. Y. Hunter's tremendously sensational novel, gives the key to the whole work. The rapid growths of insanity and suicide at the present day prove to him that civilisation "with all its magnificent results in improved sanitation and enhanced public and personal hygiene" has not strengthened the modern mind in proportion to the modern body. While the body, he says, "has benefited from applied scientific knowledge and the value of life has increased from an actuarial point of view, the mind has become hypersensitive and therefore more susceptible to disease." Of course there is much in this thesis that is arguable, but they are the writer's opinions and his book is a document in support of them.

The story is not a pleasant one, but this is no reproach to it, for it was clearly not written to please. It tells of two sisters, one weak and a wife, the other wicked and a wanton. Alice, the wanton, covets the husband of her weak sister Mary and persuades her to elope with a major, who is described as the typical profligate and who more than any figure in the book impresses us as a conventional character and not a person of flesh and blood. The major drives his poor victim mad. She escapes from his thrall to confront her evil sister in a tender love-passage, or what is on the point of becoming such, with her deserted husband. From this point onwards the story is one of unmitigated gloom. The major is murdered and Mary shares the same fate, while their double murderer Alice dies in a lunatic asylum. It would not be fair to tell more of the plot than this, although the author relies upon his insight into the psychology of his lurid creations rather than upon his construction to arouse an interest. We recommend "Can it be true?" to our readers as a straightforward story of crime and punishment, well and often powerfully written by a man who knows what he is talking about. The seamy side of life has evidently few secrets from Surgeon-Major Hunter, while a situation has no terrors for him because of its horror or its inherent improbability. Here he is a good disciple, conscious or unconscious, of Balzac, and we confess that we approve his courage.

Surgeon-Major Hunter concludes his book by wishing that the State would think proper to appoint a Health Minister to guard not only the bodies but also the minds of the people, as he considers that "sound education, firm discipline, and unwearied care are called for in the mentally delicate. The first indications of passion have to be met in order that they may not run riot." If this is the moral of his book—and it wears the air of being so—he has to face the question how far State interference would have been able to avert the series of tragedies which he has depicted. For ourselves we do not see how the State could have stopped Mary from eloping or have decided that Alice was mad in time to stop her from committing murder.

Ringworm in the Light of Recent Research. By MALCOLM MORRIS, F.R.C.S. Edin. London, Paris, and Melbourne: Cassell and Co. 1898. Quarto. Pp. 142. Price 7*s*. 6*d*.

THIS work is an expansion of a paper read at the International Congress of Dermatology in 1896. It aims at presenting a concise and critical review of the subject according to the recent observations of Sabouraud and those who have worked on the same lines, including the author himself. In this we think Mr. Morris has been successful and the book may claim to be the clearest and most concise account of the results of an enormous amount of careful and laborious work mainly accomplished by Sabouraud. Yet the outcome of it all is, in Mr. Morris's opinion, that while the main result is that the fungi which cause ringworm may be divided into small-spored and large-spored, the further division of the large-spored into numerous sub-species cannot be considered as proved and, in fact, that there is more evidence against it than for it.

The subject is discussed in twelve chapters—Introductory; the Parasitic Theory; four chapters on Etiology, discussing Sabouraud's doctrine and the researches of other workers, with a summary and comparison of results; Pathology; three chapters on the Clinical Varieties; Diagnosis and Prognosis; Treatment; and Prophylaxis. It can be thus seen that the whole subject is gone over and without repetition or undue verbiage is adequately set forth. In the chapter on Treatment the principal modes of treatment by others, as well as the author's own methods, are given. The work is illustrated with 22 beautifully executed micro-photographs by Mr. Andrew Pringle and a coloured frontispiece of the large- and small-spored fungus stained. It is altogether handsomely got up and is thus a credit to both the author and the publisher, and can be commended to all who wish to be familiar with the present aspect of the subject without wading through the details of the original papers.

LIBRARY TABLE.

Lectures on Medicine to Nurses. By HERBERT E. CUFF, M.D.Lond. London: J. & A. Churchill. Second edition. 1898. Price 3*s*. 6*d*.—At first sight this book might be thought to go too much into medical details, but on consulting the preface we find a satisfactory explanation of this. As Dr. Cuff says, an intelligent nurse will not be satisfied with knowing merely the mechanical details of her calling. She wants to know reasons, and if she is not taught by some duly constituted authority she will try to get them for herself out of medical text-books which she will not understand. Dr. Cuff has therefore aimed at supplying this want by setting out in simple non-technical language anatomy, physiology, pathology, and symptoms. All the lectures are clearly and admirably written and reasons for this or that procedure given in the simplest language. We can cordially recommend the book, not only for nurses, but for those students who are just commencing work as clerks in a medical ward.

Digitized by Google

B. Bradshaw's Bathing Places. London: Kegan Paul, Trench, Trübner, and Co. 1898. Price 2*s.* 6*d.*—The edition of this directory for the present year differs slightly from that of last year in the omission of certain of the less known springs. We think, however, that the Caucasian watering-places might have been left in, as, for instance, Piatigorsk. With regard to the glossary of technical terms at the end of the book we would point out to the editor that cyanosis is not a disease of the heart or any other organ any more than jaundice is a disease of the liver, as is the popular opinion.

Aids to Examinations. Part II. By T. REUELL ATKINSON, M.D. Dunelm. London: Baillière, Tindall, and Cox.—This little book, which, as the author candidly states in his preface, "cannot in any way take the place of the ordinary text-books," is purely an *aide mémoire*. It contains questions in anatomy, physiology, surgery, medicine, midwifery, gynæcology, and public health. The answers are clearly and fully given and the book will be found very useful as a "refresher" to the memory.

District Nursing, on a Provident Basis. By JAMIESON B. HURRY, M.D. Cantab. London: The Scientific Press, Limited. 1898. Price 2*s.*—This little volume has been written with the object of extending the system of district nursing and gives valuable suggestions for the formation of a district nursing association *ab initio*. The idea of the author is to make the association as far as possible self-supporting, or provident, in contra-distinction to one which would be dependent upon charity and we thoroughly concur with him that any organisation which raises the standard of comfort in the homes of the industrial classes and at the same time increases their self-reliance and their independence of charity is a step in the right direction. Figures are given by which it is shown that, as a general rule, in towns one district nurse is amply sufficient for 4000 persons and the annual cost of a trained nurse varies from £80 to £100. 2000 persons contributing 1*s.* per year, or 1*d.* per month, would therefore be a sufficient number to provide the necessary funds, and would place the association upon a financially sound basis. The number of visits paid by a district nurse is estimated at from 15 to 20 per day, or 5000 visits in the year. The calculation is made for a compact and thickly-populated district and here the contribution of 1*s.* per head would be amply sufficient. In rural districts, on the other hand, where the population is scattered and where it is estimated that the nurse would only be able to serve 2000 persons a larger annual subscription would be necessary. The figures given are deduced from practical experience in the working of nursing clubs and associations now in existence. There is much valuable information connected with the subject; also suggestions are given for rules and regulations such as have been found useful in establishing and in carrying on a nursing association.

Pharmaceutical Formulas: a Book of Useful Recipes for the Drug Trade, collated chiefly from the "Chemist and Druggist," with Annotations. By PETER MACEWAN, F.C.S. London: Published at the Offices of the *Chemist and Druggist*. 1898. Price 8*s.*—This is essentially a book which is calculated to save reference to a score of books before probably the desired information is found. The recipes and formulas are necessarily up to date since the materials are mostly collated from that brisk organ of the trade, the *Chemist and Druggist*. The universality of information afforded in the book will be gathered from the following outline of the sections. The first section relates to toilet preparations and specialities, the next to preparations for the hair, the next to dental preparations, while the succeeding sections are devoted to perfumes, beverages, household and domestic requisites, writing materials, varnishes, polishes, and stains, lozenges, miscellaneous preparations, and lastly galenical and medicinal preparations. A good index enables the reader at once to ascertain the information which he requires. The directions enjoined are eminently practical and evidently based upon experience. The chapter on Galenical and Medicinal Preparations may be referred to as an example. The book supplies a distinct want and is certain to give satisfactio to those by whom such a work is in constant requisition.

The Extra Pharmacopœia. Revised in accordance with the British Pharmacopœia, 1898. By WILLIAM MARTINDALE, F.L.S., F.C.S. Serotherapy, Organotherapy, Medical References, and a Therapeutic Index. By W. WYNN WESTCOTT, M.B. Lond. Ninth edition. London: H. K. Lewis. 1898. Price 10*s.* 6*d.*—The first edition of this indisputably handy compendium was published in 1883 and up to the time of the recent revision of the Pharmacopœia no less than eight editions had been published, which is a very practical proof of its usefulness and of the esteem in which it is very generally held. The ninth edition has just been issued—that is, within a very short time of the publication of the new Pharmacopœia with the revisions of and additions to which it is in complete accordance. The section of Organotherapy, by Dr. Wynn Westcott, is ably done and affords an excellent *précis* of the literature of the subject. The references are as complete and as recent as anything we have hitherto remarked. The authors merit warm praise for having undertaken what must have been no light task, and for the very excellent and expeditious way in which they have accomplished it. Though from its size the book is regarded as a pocket guide, yet it will be found to be replete with just that new information connected with the subject which every practitioner and pharmacist would do well to possess.

Guide-books.

With the near approach of the holiday season comes the annual issue of guide-books, all setting forth the attractions of the districts they respectively deal with so enticingly that it becomes a matter of some difficulty for the tourist to make up his mind where to go. This important matter having been settled at the well-known family conclave, which invariably ends in one person getting his or her way to the discomfiture of the others, the necessary guide-book is applied to. It remains for us to mention some of the places easily and inexpensively reached. In the Tourist Guide to the Continent, price 6*d.*, published by the Great Eastern Railway Company, the traveller will find in the short space of 158 pages directions how to get to Belgium, Holland, North Germany, the Rhine, Denmark, Sweden, Norway, and Switzerland. The chapter of "dull, useful information" is good with one exception, and that is a remedy taken from the *Queen* for dust or grit in the eye. "One drop of glycerine allowed to fall into the eye generally affords instant relief." It might do so by causing a copious flow of tears, being a strong irritant to mucous surfaces, but the average patient will find one drop of castor oil just as efficacious and far less painful. Apart from this the guide-book is well done.

The Swedish Touring Club's Guide to Sweden. With 15 Maps. London: George Philip and Son. Pp. 215. Price 5*s.*—This little book will prove an excellent guide to those who intend to travel in Sweden. Its appearance is that of the familiar Baedeker and it is good and practical throughout. After chapters upon general information, hotels, sports, and means of getting about, the reader will find thirteen routes and tours described in a terse guide-book style. The Swedish Touring Club is becoming a numerous body. Its income is now about £2500 a year and the members have many privileges in the way of reduced fares and tariffs. It is worked somewhat in the

Digitized by Google

way of the English Cyclists' Touring Club, with a head office in Stockholm (Fredsgatan 28) and 400 consuls scattered all over the country. At the chief office information is given free of charge to all comers, be they Swedes or foreigners, on all subjects which relate to touring. The consuls do the same for their respective districts. The club opens new tourist routes and erects signposts and mountain shelters. Visitors to Sweden are encouraged to become members, the annual subscription being about 3*s.* 6*d.* The central parts of Sweden are largely covered by pine-forests and offer a splendid health resort for townspeople. At many places fine hotels have sprung up, where during the summer season first-class accommodation and food may be found in the heart of the wildest country. The districts around Lake Siljan in Dalecarlia, and around Ostersund on the line between Stockholm and Trondhjem, and the region of the two northern rivers Indalelfven and Angermanelfven, form three separate areas each excellent for a summer holiday.

The Danish Tourist Society send us an excellent little book about Copenhagen, published in London by Simpkin, Marshall, Hamilton, Kent and Co., and in Copenhagen by H. Hagerup, price 1*s.* 6*d.* This is an admirable publication for the information and plans, tables, &c., are so clear that even a stupid person could have no difficulty in finding his way about. We are tempted to quote the following as a very happy collocation of sentences. In 1604 in the Helligaandshuset, "100 students in 8 days drank 18 casks of German beer in the place! Later on it was used as a mortuary."

JOURNALS.

IN the *Phonographic Record* for July Sir W. R. Gowers, pointing out that chorea is sometimes mistaken for hemiplegia, says that there is scarcely an exception to the rule that when a child between the ages of seven and fifteen years is said to have lost the use of one arm the malady will turn out to be chorea. Dr. Fletcher Beach, in his paper on Mentally Deficient Children, confirms the aphorism of the late Dr. Langdon Down that the prospect of educating and training these children is "inversely as the child is comely, fair to look upon, and winsome." Dr. Beach describes in detail the characteristics of mentally deficient children in a manner both authoritative and instructive. It is to be hoped that Mr. Lamming Burton's picture of the dark side of an assistant's life is either overdrawn or exceptional.

LITERARY INTELLIGENCE.—The Rebman Publishing Company's new books include a work on the "Ferment Treatment of Cancer and Tuberculosis," by Horace Manders, F.R.C.S. Eng., and the following volumes in the series of "Lehmann Medicinische Handatlanten" (Hand Atlases), English edition, which they are publishing in conjunction with Mr. W. B. Saunders of Philadelphia: "Atlas of Internal Medicine and Clinical Diagnosis," by Dr. C. Jakob of Erlangen; edited by Augustus A. Eshner, M.D., Professor of Clinical Medicine in the Philadelphia Polyclinic, Attending Physician to the Philadelphia Hospital; 68 coloured plates and 64 illustrations in the text. "Atlas of Legal Medicine," by Dr. E. R. von Hofmann of Vienna; edited by Frederick Peterson, M.D., Clinical Professor of Mental Diseases, Women's Medical College, New York; Chief of Clinic, Nervous Department, College of Physicians and Surgeons, New York; with 120 coloured figures on 56 plates and 193 beautiful half-tone illustrations. "Atlas of Laryngology," by Dr. L. Grünwald of Munich; edited by Chas. P. Grayson, M.D., lecturer on Laryngology and Rhinology in the University of Pennsylvania, &c.; with 107 coloured figures on 44 plates and 25 black-and-white illustrations. The Rebman Publishing Company have removed to new premises at 129, Shaftesbury-avenue, Cambridge-circus, W.C.

Analytical Records
FROM
THE LANCET LABORATORY.

TABLOIDS OF (1) BISMUTH SUBGALLATE; AND (2) HYPOPHOSPHITES COMPOUND.
(BURROUGHS, WELLCOME AND CO., SNOW-HILL BUILDINGS, E.C.)

BISMUTH subgallate is a salt of interesting composition which has been comparatively recently introduced in medicine. It acts as a useful check on the progress of fermentative dyspepsia and good results are recorded of the regular administration of the tabloid of 5 gr. in such cases before or after each meal. It has been employed also in typhoid fever, gastric catarrh, and in cholera asiatica, and in various forms of diarrhœa. The salt occurs as a yellowish powder, a condition which appears after the tabloid has been placed for a few minutes in water. The tabloid readily crumbles in this way so that the convenience as well as reliability of the therapeutic effect of the salt in this form is established. The composition of the tabloid of hypophosphites compound is based upon the well-known formula comprising the hypophosphites of calcium, potassium manganese, iron, quinine, and strychnine. Each tabloid weighing 1½ gr. is equivalent to half a teaspoonful of standard compound syrup, many of the drawbacks of which are surmounted by this convenient form of administration.

"ULRICUS" AND "BELVEDRA" MINERAL WATERS.
("PASSUGG," 39, EASTCHEAP, E.C.)

These waters, which are drawn close by the gorge of the Rabiusa, near Coire, Switzerland, present some noteworthy features on analysis. "Ulricus," for example, is a highly alkaline water containing an important quantity of iron in the form of protocarbonate. A distinct amount of bromine is also present. The results of our analysis were as follow: total saline constituents 6·00 grammes per litre; alkalinity reckoned as carbonate of soda, 4·92 grammes per litre; carbonate of iron, 0·069 gramme per litre; common salt 0·84 gramme per litre. The sample examined was bright and clear and under slight pressure of carbonic acid gas. The quantity of alkaline carbonate is somewhat remarkable. The water is therefore distinctly antacid and probably of value as a sedative in certain abnormal gastric conditions. A trace of lithium was also recognised. "Belvedra" is described as a chalybeate spring water, though according to our analysis the iron in it is less than in "Ulricus." It contains, however, much less mineral matter, as the following analysis will show: alkalinity reckoned as carbonate of soda, 1·80 grammes per litre; protocarbonate of iron, 0·0348 gramme per litre; and common salt, 0·029 gramme per litre. This water, like the last, contained a slight excess of carbonic acid gas. Though containing an important quantity of iron it was clear and bright. It may be used after the manner of an ordinary table water with the difference and probable advantage in some cases that it contains iron in a well-known assimilable form.

TEMPERANCE BEERS.
(THE BANKS BEER CO., LTD., THE BREWERY, BLENHEIM-ROAD, HORNSEY-ROAD, LONDON, N.)

We have examined three or four types of the non-excisable beverages of this company with the following results. Pale ale: extractives, 1·28 per cent.; mineral matter, 0·10 per cent.; alcohol, by weight 0·53 per cent., by volume 0·66 per cent., equal to proof spirit 1·16 per cent. This ale possesses a delicate bitter flavour and is slightly charged with carbonic acid gas. Mild ale: extractives, 1·66 per cent.; mineral matter, 0·10 per cent.; alcohol, by weight 0·53 per cent., by volume 0·66 per cent.,

Digitized by Google

equal to proof spirit 1·16 per cent. This specimen possessed slightly more "body" than the previous one, having a decided malty flavour, together with that characteristic of the bitter principle of the hop. Stout: extractives, 2·28 per cent.; mineral matter, 0·11 per cent.; alcohol, by weight 0·53 per cent., by volume 0·66 per cent., equal to proof spirit 1·16 per cent. As might be expected the stout contains more extractives than either of the previous samples. Its flavour distinctly suggests ordinary brewed black beer. As will be seen the quantity of alcohol is negligible and nearly a half below the excise limit. The beers were in perfectly sound condition and evidently prepared from malt and hops and not substitutes. We could find no objectionable preservative. In regard to the ginger-beer we did not find it satisfactory. On removing the stopper most of the liquid was lost through violent effervescence and what liquid was recovered was not of a particularly agreeable character. Perhaps the ginger-beer was too young or had been exposed to a too high temperature.

TURTLE JELLY.

(T. K. BELLIS, 6, JEFFREYS-SQUARE, ST. MARY AXE, E.C.)

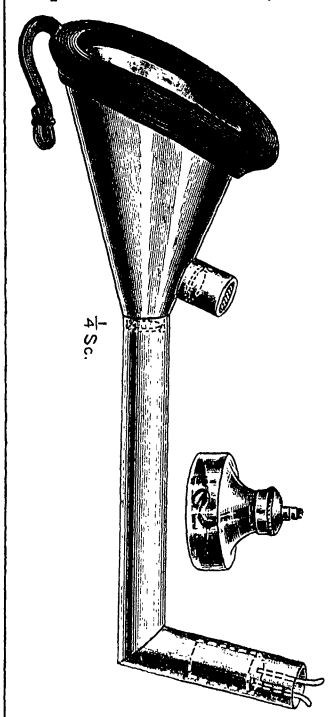
Turtle jelly is an excellent preparation for patients who requiring a nourishing article, find it inconvenient to take it in the form of warm soup. The jelly is practically clear and possesses that peculiarly agreeable flavour for which turtle soup is highly esteemed. Obviously if desired the jelly may be soon converted into soup by merely warming. In the form of jelly, however, and of course cold, it will often be more acceptable. The jelly is contained in glass jars sealed with a cork cap protected by a capsule.

(1) IODOFORMOGEN; AND (2) TANNALBIN TABLETS.

(B. KÜHN, 36, ST. MARY-AT-HILL, E.C.)

The idea of combining iodoform with albumin, giving rise to a compound which has been called iodoformogen, is ingenious and one presenting certain distinct advantages. Thus iodoformogen has little or no smell, is non-hygroscopic, and occurs in the condition of a fine powder, which it is said does not "lump." In short, iodoformogen would appear to be much superior for the purposes of dressing wounds to iodoform itself, as while exhibiting the antiseptic properties of iodoform it permits of more uniform dusting, the grains clinging more intimately to damp surfaces than is the case with iodoform. Tannalbin is now well recognised as a useful but non-toxic intestinal astringent. It is particularly servicable for checking diarrhœa. This is to be attributed to the fact that while it is insoluble in the gastric juice, producing no disturbance in the stomach, yet it dissolves slowly in the intestinal fluids producing an astringent effect. The compound is prepared from albuminate of tannin by exposure of the substance to a temperature of 110° or 120° C. for five or six hours. The tablets contain five grains of the compound and they afford a very convenient means of administering it.

HARZBACH MINERAL WATER.



(BROWN BROTHERS AND CO., 35 AND 37, WASHINGTON-STREET, GLASGOW.)

According to our analysis Harzbach water is a mildly alkaline carbonated water suitable for table purposes. The alkalinity of the water reckoned as carbonate of soda was found to be equivalent to 0·84 gramme per litre; the salt amounted to 1·98 gramme per litre. It contains also minor constituents — as, for example, carbonate of magnesia, sulphate of lime, and traces of lithium salts. Amongst the specimens we examined some were not satisfactory, one having parted with the excess of carbonic acid gas and another being of a distinctly yellowish colour. Further, on heating the solid residue a very distinct blackening occurred due to organic matter. The method of stoppering the bottles is novel. It consists of sealing the bottle with a thin layer of cork bound down by metal capsule, so bound under the lip of the bottle as to be firmly attached even though there is considerable pressure within. It is probable, however, that this method of stoppering accounts for some of the unsatisfactory results which we have recorded.

New Inventions.

AN ORI-NASAL INHALATION TUBE.

THIS instrument is for the purpose of inhaling the vapour of drugs such as menthol, oil of eucalyptus, pinol, and many other substances, in a far greater degree of efficiency than has been hitherto possible with other forms of instruments. It consists of a long tube, at one end of which is a mask with metal valves. The mask fits over the mouth and nose. At the other end is a small moveable tube made to open at either extremity and covered at these points by caps of coarse wire gauze, and this tube is to contain the drug to be employed. All parts of the instrument are made of plated metal. The mask is fitted with a comfortable rubber covering. This instrument will prove of much value in cases of throat and lung affections, nasal catarrh, coryza, or cold in the head, and other similar complaints. The chief advantage with this instrument is that heat may be employed by means of the flame of a spirit-lamp in the vicinity of the drug tube, towards the extremity of the apparatus. By this means an immense amount of vapour is given off from the drug which has been employed, and the patient inhaling this concentrated vapour naturally derives a far greater degree of benefit. The ori-nasal inhalation tube being made of metal is not liable to injury like instruments made of glass or china, &c. Another point is that being made of metal it can be readily cleansed with hot water, thus thoroughly purifying it. The instrument is manufactured by Messrs. S. Maw, Son, and Thompson, 7 to 12, Aldersgate-street, London, E.C.

Somerley, Reading. H. HIBBERD BEALE.

UNITED HOSPITALS ATHLETIC SPORTS.—The annual athletic competitions among the London hospitals were held at the London Athletic Club Ground, Stamford Bridge, before a small but enthusiastic gathering of spectators on Saturday, July 9th. The programme consisted of 12 events, 11 of which constituted the contest for the Hospitals Challenge Shield. St. Mary's was again, for the third year in succession, successful with 5 firsts, Guy's and St. Bartholomew's having 2 each. The performances of F. W. Sime (Guy's), A. G. Butler (St. Mary's, who beat the hospitals ½-mile record held by himself), C. E. H. Leggatt (whose high jump of 5 ft. 9 in. also beat the record held by himself), and R. C. Leaning (St. Mary's), were excellent; while in the invitation race of 1½ miles the four miles champion, C. Bennett, only just failed to beat the present record.

THE LANCET.

LONDON: SATURDAY, JULY 16, 1898.

IT is impossible to doubt that the action of the General Medical Council in the matter of imposing further restrictions on the employment of unqualified assistants by registered practitioners has met with the general approval of the profession. We have given free admission to correspondence on both sides of this question. We have not been insensible to the hard bearing of the Council's new Regulation or Notice on a certain limited number of men who, having passed through a regular curriculum of study, have, from no fault of their own, been unable to qualify. We have even admitted that the Council's slow and halting action in the past in discouragement of the employment of unqualified assistants has given the profession an impression that, under certain conditions of supervision, such employment would not be condemned. But nevertheless, looking at the accumulating evidence of the misuse and abuse of this license, at the growth of a strong public sentiment against it, at the extensive deception practised on the public by it, and at the manifest injustice of it to registered members of the profession, especially to the younger members, it is clear that the time had come for the Council to advance in the matter and to increase the stringency of its regulations. It is equally clear that the weight of public and professional opinion is in favour of what the Council has done. There have been, of course, a few protests and complaints. In the ranks of the unqualified there are men who have been found very handy, very honest, and very serviceable. Years of experience in a general practice do give a certain education and aptitude. Besides, such men have fulfilled duties of management and of book-keeping and dispensing, necessary duties, the delegation of which greatly relieves the busy practitioner whose clinical duties absorb a large portion of his time by day and by night. It is possible that without any violation of the Council's regulations a few of the best class of the unqualified, whose age makes any other calling impracticable, may still be retained for the performance of such duties. It may be admitted that there is something in the complaint of practitioners in some parts of the country that they have a difficulty in getting qualified assistants. The committee of the General Medical Council seemed satisfied with the evidence on this point. But we can scarcely believe that this difficulty will be of long duration. The average annual excess of supply of new practitioners over the annual loss in the way of death is for the last five years 882. Even last year, when the number of new registrations was less than it had been for nine years, there was an excess of supply over loss by death of 648. In the face of such figures we may conclude that the difficulties alleged to exist at present are due to temporary causes and chiefly to some misunderstanding between the parties affected by the new regulations—principals on the one hand and qualified assistants on the other. We claim to have given our correspondents on both sides of this question a fair hearing, and we must admit that both sides have shown considerable skill in stating the facts and the conclusions as they present themselves from their respective standpoints.

The time has come for facing what is practically a new departure. Principals and assistants will now do well to see how they can best meet each other's objections and accommodate themselves to actual facts. Some of our correspondents have described vividly the hardships of the life of a qualified assistant—his modest salary, his humble fare, and his hard work. One of them described his work as "slavery, night and day," and said that, as a rule, he had found principals "very selfish." This assertion is refuted by "Practitioner" in THE LANCET of July 9th in a very forcible letter, and we believe that most of those who have had experience of assistantships will say that principals are very like men in other arduous and unremunerative professions who have enough to do to "make ends meet" and to distribute with fairness their modest income between the claims of their family with a necessary establishment on the one hand and their assistant on the other. Not a few such in the after periods of life will look back to their assistantship as one of their most useful experiences, and will recall their principals with every sentiment of respect and friendship.

A young man, emerging from a period of prolonged study and costly education, having succeeded in getting on the Medical Register naturally thinks that his time for remuneration and reward has come. He has been familiar for years with men, his teachers, at the head of their profession, who keep large establishments and expensive carriages and evidently enjoy considerable incomes. He is apt unthinkingly to apply such standards of comfort and dignity to members of the profession generally. Unlike his seniors in practice he has had little experience of private practice and its standards of remuneration, and if in his first assistantship he chances to be located in a small town or a poor rural district he will probably experience a considerable disillusionment. If he is a man of sympathy and imagination he will put himself into his principal's place and make allowance for his difficulties. If he is not endowed with these qualities he will be dissatisfied with his environment and will vent his censure on the unfortunate principal who may be very little to blame. For he is only one of 30,000 men of the profession. He is responsible, of course, for his own character and for the treatment of his assistants, but for the general state of the profession, for the competition in it, for the loosely administered charities which spoil it, and for the low conceptions in the public mind as to the remuneration of medical men his responsibility may be of the very slightest. This last is the real evil which has to be grappled with and for the cure of which principals and qualified assistants must strive together. The employment of the unqualified assistant did give some excuse to those who made light of medical claims; but the Regulation of the General Medical Council will be a stimulus and unanswerable argument for medical practitioners to demand higher rates of remuneration with

Digitized by Google

which they may adequately pay those assistants who bring full qualifications to their work and whose education has extended over years.

THE social and sanitary problems of Liverpool do not differ essentially from those met with in certain other large towns, but the scale on which they may be studied and the graphic way in which they have been set forth in the annual reports of the successive medical officers of health have served to invest them with peculiar interest. Accordingly we have frequently devoted a leading article to the subject or to its principal features with a view to excite interest and to give encouragement to those whose arduous duty it is to make life longer, healthier, and pleasanter in a community which for many years enjoyed among English towns a pre-eminence in overcrowding and all the variety of evils which that condition involves. We have lately shown the difficulty of arriving at quite accurate data as to the population of the city in the long intercensal periods, and allowance for error under this head must always be made; but, even so, the broad figures and facts of the last report include subjects which are worthy the attention of all medical men and of all who realise the part played by municipal government in the application of medical and hygienic science to the wants of large populations. We chance to have on our table two reports of the health of Liverpool—one for 1869 and the other for 1897. The most pessimistic student of modern civilisation must admit the great strides which have been made in improving the health of the most crowded communities and in bringing large classes of deadly disease under comparative control.

Let us take, for example, the case of tuberculous diseases. We are fain to think that if mortality from this class of diseases can be materially reduced in such a community as Liverpool we need not despair of bringing any kind of disease into subjection. This has actually been achieved in Liverpool. The annual average death-rate per 100,000 of the population at all ages from all forms of tuberculosis is given for three decennial periods, as well as for that of 1896-97. The decline is steady. But for greater clearness we will give the comparison of the rate of the decade 1866–75 with that for the last year. For the former period it was 430·8 per 100,000; for the last year it was 258·2. It will be remembered that this improvement has come mainly from broad improvements in sanitation. We are on the eve, it is to be hoped, of seeing many special measures for dealing successfully with this great evil, founded on discoveries, bacteriological and otherwise, which were not made in the decade to which the first statistics apply. It is gratifying to find that the health authorities of Liverpool are availing themselves of the assistance of bacteriological experts in dealing further with this tuberculous problem. In the meantime it is satisfactory to know that, by the ordinary action of their by-laws, by improvements in property, and by the wholesale destruction of large insanitary areas, such great and significant improvements have already been wrought.

We may at this point say a word in strong praise of the sanitary authorities of Liverpool for one other act of enlightened municipal wisdom on their part. Dr. HOPE, the medical officer of health, on page 183 of his report for 1897 says: "The Committee have provided at each one of the city hospitals [isolation] a supply of antitoxin which is given to any medical practitioner making application for it." We know that in other large communities, probably in most, no such provision exists and that public authorities, which are keen to expend many thousands of pounds on large buildings and in other ways, make no provision for supplying promptly and purely an article on the easy and early procuring of which by medical men the saving of life in cases of diphtheria often depends. A comparison of the two reports for 1869 and 1897 shows a great improvement in diagnosis. In the 1869 report, as Dr. HOPE points out, all continued fevers were included under the generic term of typhus—i.e., so-called gastric fever, enteric fever, low fever, continued fever, brain fever, bilious fever, relapsing fever, and typhus fever. Such a method, of course, vitiated the statistics and all conclusions from them. The present report shows a great advance and gives sharp and precise returns of the different forms of continued fever. There survives, however, in the report for 1897 a distinction in diagnosis of very dubious propriety. On page 38 the number of deaths from diphtheria is given as 91; on the next page the deaths from croup and membranous croup are given. We will not say that there are no such diseases as croup and membranous croup distinct from the disease produced by Löffler's bacillus, but we venture to suggest that a closer examination of such cases will very greatly reduce the distinction and identify the cases as diphtheritic ones. The zymotic mortality of Liverpool is still, of course, very large, in spite of the reduction in the number of people living in cellars, the notification system, the creation of isolation hospitals—which are increasingly popular and absorb 54·6 per cent. of the cases of scarlet fever—and other sanitary measures. Typhus fever can still be studied in Liverpool. There were last year 158 cases, of which 23 resulted fatally. There is a gradual decline of typhoid fever, but it still reigns, and the report includes a very well-tracked instance of a small outbreak among 27 children who had, all but two, eaten ice-cream sold at a fair. The two had eaten chip potatoes procured from the same vendor in whose house a case of typhoid fever was found. Infantile diarrhœa still asserts itself with great force and kills nearly as many as all the other epidemics put together. Still, the impression made by the report is that new forces of health and hygiene are gradually gaining the ascendancy. There was not one death from small-pox, but Dr. HOPE does not disguise his apprehensions at the discouraging aspect of vaccination legislation. He admits the value of isolation measures, but like all medical men knows how inadequate this measure will prove in the absence of systematic, conscientious and repeated vaccination.

We must not close this notice of the social and sanitary problems of Liverpool without allusion to one great factor in its sickness and mortality—that of intemperance—the more so as Dr. HOPE devotes, with no exaggerated estimate, two pages to the subject. He does not hide his sense of its gravity as an influence comparable to that of zymotic disease. As a *direct* cause of death it shows a

Digitized by Google

slightly higher figure than in the preceding year and has been more fatal than scarlet fever or all the other forms of fever combined. And in its remote and indirect mischief he thinks drink even farther reaching and much more insidious than zymotic sickness, and this in spite of an exceptional decrease in the arrests for drunkenness. The latter are no guide as to the degree in which alcohol is used so as to be pathogenic, which Dr. HOPE evidently considers to be still very serious. "There was no evidence," he says, "that excessive drunkenness in the homes of dwellers in the more squalid regions has materially diminished." It is awkward when there is such a discrepancy between the medical and the police reports of this vice; but it is certain that the medical is the more reliable and will have to be reckoned with before the health of Liverpoo or any such community can be placed on a satisfactory footing.

THE House of Commons Committee having concluded its labours on the Vaccination Bill we may glance at the principal results achieved. In Clause 1 the infantile vaccination age limit has been fixed at six months as in Scotland and a provision has been added that no regulation of any hospital or institution shall override this enactment by fixing an earlier age. The public vaccinator's domiciliary visit is to be made at four months instead of nine months, as proposed when the age limit was intended to be one year. An important alteration has been made with regard to the description of the lymph to be used. In a former article we pointed out that the phrase "glycerinated calf-lymph" was insufficient to prevent any mixture of glycerine and calf-lymph, however carelessly made, being used under the Bill. The clause now runs that the public vaccinator "shall offer to vaccinate the child with glycerinated calf-lymph or such other lymph as may be issued by the Local Government Board." This really amounts to a guarantee that all lymph so used shall have been prepared with the greatest care and in the light of the most recent knowledge. Where the public vaccinator finds a house so unhealthy as to be dangerous to an intended vaccinee he shall postpone the vaccination and send notice to the medical officer of health. Clause 3, the obscurity of which caused much debate, has been altered and simplified as follows: "The Local Government Board may make rules and regulations with respect to the duties and remuneration of public vaccinators, whether under contracts made before or after the passing of this Act." A new clause provides that when small-pox threatens, or in other exceptional circumstances, the Local Government Board may issue an order requiring any board of guardians to make temporary provision of vaccination stations. In any future imprisonments under the Acts the prisoners are to be treated as first-class misdemeanants.

A fortnight ago, in commenting on the defeat of Sir WALTER FOSTER'S amendment providing for a declaration of conscientious objection, we indicated that there was a danger that this defeat might prevent perseverance with amendments for the inclusion of revaccination in the scope of the Bill. At the same time we urged that these amendments should still be pressed, even subject to a conscience clause as regards revaccination, and we suggested that though the scheme would be illogical there would he no special difficulty in applying such a clause to revaccination even if no alternative to penalties were to be allowed as regards infantile vaccination. As a matter of fact during the final sitting of the Committee a conscience clause was passed, but, curiously enough, it applies neither to vaccination of infants nor to revaccination of children before leaving school. At four years of age children who have not been vaccinated in infancy, and whose parents have been penalised under Section 29 of the existing Act, may again be dealt with, this time under Section 31, and a penalty again enforced. But relief from this second penalty may be obtained by the parent satisfying the court that he entertains serious objection to vaccination. This amendment was carried against the Government by a combination of supporters of vaccination, such as Sir WILLIAM PRIESTLEY (who proposed it), Sir CHARLES CAMERON, Sir CHARLES DALRYMPLE, Mr. MONK, &c., with the pronounced anti-vaccinationists on the Committee. On the whole, the amendment has our sympathy, though Mr. T. W. RUSSELL pointed out that, owing to changes of abode and to the want of any provision for obtaining information regarding unvaccinated children of four years old, its application will be very much limited. Whether the Government will accept it on the report stage in the Commons remains to be seen. Its adoption by the Committee serves at any rate to justify our contention that the loss of the conscience clause as concerns infantile vaccination formed no insuperable obstacle to the adoption of revaccination, with a proviso for the relief of "honest" anti-vaccinationists. That being so, we are bound to express our opinion that a blunder was committed by medical members of the Committee in not moving the revaccination amendments which had been put on the notice paper and which could easily have been further altered by incorporation of a provision allowing for conscientious objection. Of course, no such amendment could have been carried against the Government, as there would have been in its support no combination like that which defeated Mr. CHAPLIN in his opposition to Sir WILLIAM PRIESTLEY'S clause. But the amendment would at least have forced Mr. CHAPLIN'S hand and would have crystallised before the Committee the opinion of the medical profession as to the clamant requirement of the time for the prevention and control of small-pox epidemics. Even yet, in the Commons or in the Lords, it is most desirable that this question should be definitely brought forward, so that, whatever be the fate of the Bill, and whatever be the decision of the legislature, the responsibility with regard to a provision for national revaccination shall be laid on the shoulders which ought to bear it.

In his oppostion to the clause providing for the payment of private practitioners for properly performed vaccinations Mr. CHAPLIN had the support of what we may call the anti-vaccinationist section of the committee, and here also he was successful. The rejection of this clause, the non-adoption of revaccination and the bungling as to conscientious objection are the outstanding features of the

Digitized by Google

Committee's work on the Bill. They leave it a mere make-shift which will do no credit to the Government and which will not be effective either in drawing the teeth of the anti-vaccinal agitation or in increasing the national protection against small-pox. It is a very poor outcome of the seven years' labours of Lord HERSCHELL'S Royal Commission.

Annotations.

"Ne quid nimis."

THE TEACHING OF TROPICAL DISEASES IN LONDON

THE letter of Sir Henry Burdett and the leading article based thereon in the *Times* of July 11th will bring to a focus the question of the formation of a school for studying and teaching tropical diseases in London. At the suggestion of Mr. Chamberlain the committee of the Seamen's Hospital has placed before him a scheme which practically amounts to an enlargement of the branch hospital at the Albert Docks from 20 to 45 beds, and the building of school premises, museum, and laboratory, with accommodation for from 20 to 25 students, of whom 10 would be able to sleep on the establishment. A medical tutor is to supervise the instruction for six hours daily, whilst the staff of the Seamen's Hospital as well as of the branch hospital, with specially selected additional teachers, are to attend and teach for four hours a day during four days a week. We see no provision in Sir Henry Burdett's letter for the payment of this staff of teachers. It can scarcely be expected that the physicians and surgeons attached to the Seamen's Hospital Society can undertake any more gratuitous work than they have at present. The Albert Docks is not a very accessible place and a visit there, with four hours' teaching, will make a serious inroad into a physician's or surgeon's daily work. The study of tropical diseases is of the utmost practical importance for colonial and military surgeons and practitioners and deserves every encouragement. Hitherto it has been best carried out at Netley and the amount of practical material in that hospital for such a study must not be ignored, although it is only at the disposal of the Indian and army medical officers. Sporadic courses of lectures in London are eminently unpractical because the students cannot watch the course and treatment of the cases illustrating the lectures. Few patients can be brought from Greenwich or the Albert Docks to a metropolitan school and few students will regularly visit either of these institutions. Sir Henry Burdett is sanguine that tropical diseases can be thoroughly studied at the docks and on behalf of the Seamen's Hospital appeals to the public for £10,000 and a net income of £2000 a year, in addition to a capital grant of £3550 from the Colonial Office and the fees from colonial students, estimated at £1000 per annum. We see no statement as to the number of tropical cases which are admitted into the hospitals of the Seamen's Hospital Society. Chronic dysentery, beri-beri, and chronic malaria make up almost entirely the tropical diseases which a student may expect to see during a course of three or four months' study, and acute cases must be extremely rare, judging from the annual reports of the society. Mr. W. Johnson Smith has published the records of the cases of hepatic abscess during twenty-five years and they only amount to fifty. Bacteriological investigation in tropical diseases can be taught in the well-appointed laboratories of many of our medical schools and is a part of the Netley curriculum. Phthisis, cardiac disease, rheumatism, and renal disease figure amongst the most common cases of illness at the Seamen's as well as at other hospitals. If compulsion is exercised on applicants for Colonial medical appointments, as seems to be implied in Mr. Chamberlain's letter, of course a regular supply of students will be at once forthcoming; but if there is no compulsion we question whether many will attend at such an inaccessible situation as the Albert Docks, and we doubt whether the variety of cases is sufficient to interest and instruct them for such a long period as three or four months.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE recent election of members of the Council of the Royal College of Surgeons of England, the result of which we published last week, was somewhat remarkable. Practically there was only one vacancy, as two of the former members, Mr. Langton and Mr. Morris, re-applied; and evidently many electors considered that this vacancy should be filled with a representative from the provinces. Mr. Richardson Cross, who headed the poll, received 411 votes, and of these 74 were plumpers. We believe this large number of plumpers is unprecedented, but it is still more curious that if he had not had even one of these plumpers he would still have been 12 votes ahead of the candidate who polled the next highest number of votes. The votes recorded for the two late members of Council who re-applied were nearly equal, Mr. Morris polling 325 and Mr. Langton 322 votes. We congratulate Mr. Cross on his election and we feel sure that he will prove a valuable addition to the Council. 651 voting papers were received by post—a larger number than on any previous occasion; but against this must be put the very small number of personal voters; in all there were only 26 and the number would be even smaller if it were not that several Fellows have been so long accustomed to vote personally that they do not like to give it up. On some recent occasions it has been found difficult to get the 6 Fellows present (exclusive of the members of Council) who are necessary for the commencement of the election under the Charter. The meeting of Fellows summoned by the Council for 5 o'clock on the same afternoon proved a failure. Only 26 Fellows were present and of these 8 were members of Council, but the quorum required by the by-laws of the College is 30 and therefore no meeting was held. A similar occurrence took place last January and in consequence the Council decided to call only one meeting of Fellows each year, and it was thought that the election of members of the Council would bring Fellows to the College, therefore the Fellows' meeting was summoned on the same day. Even on some occasions when a quorum was obtained there were no agenda beyond the confirming of the minutes of the previous meeting. All these signs point to an early abandonment of the meetings of Fellows unless the Fellows bestir themselves and put on the agenda paper resolutions for discussion which will attract at least sufficient Fellows to form a quorum. When we look back on the long and difficult struggle to get the Council to call meetings of the Fellows apart from the Members we cannot help thinking it would be a very great pity if these meetings should cease to be.

THE FIGHT AGAINST TUBERCULOSIS.

THE necessity for making some defensive efforts against tuberculosis is now fully recognised and we are glad to see that the question is being widely discussed. At the annual meeting of the North of England Branch of the British Medical Association, held on July 11th at Sunderland, the President, Dr. William Robinson, delivered an eloquent address on the Repression of Consumption and the Need for the Erection of Open-air Sanatoria in England. After giving an account of the way in which phthisis is spread and

Digitized by Google

referring to the ravages which this disease commits Dr. Robinson pointed out the absolute necessity of strict hygiene being observed in workshops and the like as well as of careful and systematic inspection of meat and milk. Passing on to the question of sanatoria he said:—

"We have no drug which will kill the bacillus when lodged in the tissues, though so easily disposed of in the spittoon. All our remedies only help the host to fight the invader. Yet consumption is curable, for we can all look back on many cases in which the disease has become quiescent. The records of the post-mortem room also teach us how large a proportion of those dying of other diseases or of injuries show evidence of healed tuberculous lesions in the lungs. Fresh air and sunlight alone mean death to the bacilli and life to the patient. It is nearly 40 years since Brehmer established at Gobersdorf, in Silesia, the first sanatorium for the open-air method of treatment of consumptives and the results obtained there have been excellent."

There is one point to which Dr. Robinson did not draw attention and that is the enormous benefit which would accrue were the Smoke Prevention Acts rigorously carried out, not only in London, but in every large town. For months past the air of London has been fouled by filthy smoke arising from the chimneys of hotels, restaurants, and factories, and all this on the plea that smokeless coal cannot be obtained. The County Council have done their best, but some magistrates will not convict and others who do fine the offenders in such small sums that it is cheaper for them to poison themselves and their neighbours than to take the steps which would rectify the evil. Another matter which should be insisted upon is that no new houses should be built which are not fitted with appliances for smoke consumption. If smoke were prevented the hours of sunlight which town-dwellers enjoy might be doubled, and sunlight is a deadly foe to the tubercle bacillus.

A PHYSICAL BASIS IN THE DRUNKENNESS OF WOMEN.

THE inquiry into the liquor laws has been varied and enlivened by the evidence of Mr. Lawson Tait, who may generally be relied on to strike out a line of his own. He is very kind in his estimate of female drunkenness which he entirely differentiates from that of the coarser sex. He does not admit that it is increasing. On the contrary, it is diminishing. With a remarkable confidence he comes to conclusions different from those of other observers and finds in the lowest class of women infinitely less drunkenness now than there was thirty years ago. But Mr. Tait's chief point is that it has a physical basis in the constitution and the sufferings of women, mental or physical. The average age of the majority of the patients whom he has seen was forty-eight years, and so he has no hesitation in associating it with the change of life. In the minority, whose average age was twenty-six years, there was definite physical suffering. Mr. Tait is doubtless right in recognising a certain connexion between the multitudinous pains and ailments of women and the use of stimulants. But few medical men, we apprehend, and fewer gynæcologists, would venture to recommend alcohol for such sufferings as he does. Mr. Tait rather suggests the objection to his own prescription when he shows that in so many women it leads to excess and to almost incurable degradation. Certainly most medical men will agree that a woman is in considerable risk who uses alcohol as a remedy for her periodical troubles. Such treatment is little better than the use of laudanum and little less likely to end disastrously. Equally doubtful in our opinion is Mr. Tait's defence of the grocers' licence. He says that drinking among women is nearly always secret. A very rough observation of what goes on in the street seems to show that an increasing number of women use the public-house. Older men than Mr. Tait think this an enormous change for the worse as compared with what they saw in their earlier days. But undoubtedly there is a stage in female drunkenness when it is secret and furtive. And this form of drunkenness is immensely favoured by grocers' and confectioners' licences.

MEDICAL GRADUATES' COLLEGE AND HOSPITAL.

ON Thursday next, July 21st, at 5 P.M., there will be held a meeting of the medical profession in the building purchased for this College, 22, Chenies-street, Gower-street, W.C. Sir William Broadbent, Bart., will preside and full information will be given as to the objects of the institution. The premises can be inspected at any time and the attendance of all medical men at the meeting is invited. Full information can be obtained from Dr. Fletcher Little, 32, Harley-street, Cavendish-square, W.

LEAD AS AN ABORTIFACIENT.

AT King's Norton on July 9th an inquest was held by Mr. E. Docker, coroner for North Worcestershire, on the body of a married woman, aged twenty-three years, whose death resulted from acute lead-poisoning. It was shown at the inquest that the deceased, whose health was described as having previously always been excellent, had been taking diachylon made into pills for the avowed purpose of bringing on a miscarriage. Some days before the fatal issue she had complained of the "use" leaving one of her hands. Subsequently she was seized with violent cramps and pains, writhing in agony, with blood running from her mouth, and she never rallied. Dr. G. F. Crooke, formerly pathologist to the General Hospital, made a post-mortem examination and stated that he had seen the same effects produced from lead-poisoning in the Potteries and also in an asylum at Dresden. He had no doubt that the deceased died from the effects of acute lead-poisoning. The practice of taking diachylon to bring on abortion is not an uncommon one in the locality referred to and in adjoining districts. Such conduct must be considered as highly reprehensible and dangerous.

BALLOON NAVIGATION.

IN the *Archives de Médecine Navale* for June Dr. Le Dantec concludes an interesting article on "Climates in General and Hot Climates in Particular" with some observations on aerial navigation. In 1894 MM. Dex and Dibos proposed to cross the African continent in a balloon from Inhabimbi on the eastern coast to St. Paul de Loanda on the western, making use for the outward journey of the *alizés* or trade-winds which blow periodically at a low elevation from the south-east and for the return journey of the compensatory currents which are to be met with on a higher level. So far, however, the project, though pronounced feasible, has not been attempted. An aerial traveller desirous of visiting Lake Chad or any part of Central Africa, instead of going all the way round by Senegal could take advantage of the north-eastern *alizé* in order to traverse the Sahara, starting either from Tunis or from some place in Tripoli. On the Asian continent the south-eastern monsoon might be utilised for the conveyance of building material and stores to the otherwise inaccessible Himalayan peaks, where observatories could with advantage be erected. Finally, in the opinion of the above-mentioned travellers, if it should happen that France were to find herself once more engaged in war with Germany it should be practicable to organise speedy and regular communication with Russia by means of the constant south-westerly winds. Doubtless, adds Dr. Le Dantec, these aerial itineraries may at first sight strike the reader as verging on the fantastic, but fifty years ago when Maury first published the results of his studies the schemes which he drew up were looked upon as equally visionary.

Digitized by Google

The event has proved that the distinguished American meteorologist was right in every particular. It may, in fact, be said that owing to his researches the duration of sailing voyages has been shortened by one half. Formerly the speediest vessels used to take 180 days between New York and California, but now they can cover the distance in 100 days or less. A well-found ship following the old route could not sail from England to Sydney and back under 250 days, but, since Maury pointed out the advantage of circumnavigating the globe *viâ* the Cape of Good Hope while outward bound and Cape Horn while returning, the double voyage can be done in about four and a half months. The cosmic laws formulated by Maury being equally applicable to aerial navigation Dr. Le Dantec believes that the time is not far distant when journeys above the surface of the earth will be undertaken as a matter of course. Andrée has made a commencement and his example will soon be followed in regions where nature has raised fewer barriers. In this connexion it is interesting to note that Lieutenant Hourst, a French officer who has already made a name as an explorer, is about to undertake a balloon voyage across Africa; so that it is possible that Jules Verne's "Dr. Ferguson" may at no very long interval of time become a real instead of fictitious person.

THE TREATMENT OF CONTRACTURE OF THE BLADDER BY HYDRAULIC PRESSURE.

THE Johns Hopkins Hospital *Bulletin* of May contains an important paper on this subject by Dr. H. Young. Since the opening of the hospital in 1889 cystitis has been treated by vesical irrigation performed without the use of a catheter, hydraulic pressure being used to force the fluid through the urethra. It occurred to Dr. Young that this method might be used to dilate the bladder in cases of contracture from chronic cystitis. He reports eight cases, in all of which it proved most successful. For example, a man had suffered from severe chronic cystitis for 14 years. The urine was alkaline and contained pus and blood, and micturition occurred every 10 or 15 minutes. He had been treated in numerous hospitals with internal remedies and by local irrigations through the catheter with only temporary relief. Under hydraulic pressure 22 c.c. was the largest amount that the bladder would hold without severe pain. He was treated with irrigations of Thompson's fluid at a pressure of 4 ft. He rapidly improved, the urine became acid, the capacity of the bladder increased to 115 c.c. in 18 days and to 250 c.c. in 2 months, when he could retain his urine for 4 hours. A year after the treatment was begun there was no tendency to recurrence. Some points in the technique of Dr. Young's method may be mentioned. A conical urethral nozzle which will fit tightly the meatus is required. The patient lies on his back. The bag containing the fluid is elevated 3 or 4 ft. and the urethra is alternately distended and emptied to clean the anterior urethra; the nozzle is then pressed tightly into the meatus and the bag is raised to an elevation of about 7 ft. The urethra will become ballooned and for a time the flow will stop; soon the sphincters give way and the fluid enters the bladder and the patient experiences a sensation of fulness and gradually increasing pain. The nozzle is withdrawn and the fluid is ejected with considerable force. The operation is repeated until a quart of fluid has been used. Bland fluids, such as Thompson's or boric acid (2 per cent.), are the most satisfactory in general; silver nitrate (½ gr. to 1 oz.) may be used occasionally. The effect of the dilatation is probably to separate or loosen bundles of fibrous tissue and to smooth out pockets in the mucous membrane and also to give the antiseptic the best opportunities of acting on the mucous membrane. Is there any danger of ureteral reflux and of the carrying of pus or organisms up to the kidneys? As a result of his clinical experience and of experiments on the cadaver and on dogs Dr. Young concludes that there is not.

THE RETIREMENT OF SIR WILLIAM FLOWER.

ALL medical men will learn with regret that the state of Sir William Flower's health compels him to resign his appointment as Director of the British Museum, Natural History Branch, at South Kensington. Sir William Flower, K.C.B., who is President of the Zoological Society, was for twenty-three years conservator of the museum of the Royal College of Surgeons of England, in which capacity he earned the general admiration of the scientific world for his valuable contributions to the morphology and classification of the mammalia. He takes into his well-earned retirement the good wishes of his medical brethren, who are proud to remember that a man of such brilliant learning is a member of their own profession.

NEW LABORATORIES AT THE LONDON SCHOOL OF MEDICINE FOR WOMEN.

THE laboratories at the London School of Medicine for Women in Handel-street, Brunswick-square, which have been recently built, form a large block of four storeys and comprise a dissecting-room and laboratories for physiology, chemistry, and physics, with accessory rooms. The dissecting-room is on the second storey; it has a granolithic floor and a tiled dado, so that the whole room can be washed with a hose; above the dado slates for drawing are fixed and form almost a continuous row. The room is lighted by electric lamps and is ventilated by a turret and a cowl. The physiological laboratory is intended for 70 students and is fitted with benches; the three rows of benches which are nearest the windows are fitted for microscopic work, while a fourth row is intended for experimental physiology and has recording cylinders the revolutions of which are worked by an electric dynamo. An arc lamp is also provided for a magic-lantern and the window blinds are light proof so that the room may be completely darkened. The chemical laboratory is not yet completely finished; it will contain tables for about 70 students, and an adjoining room is fitted up as a private laboratory for the lecturer. The basement floor is intended for a physical laboratory. A second and a third block will have to be built before the buildings are complete. The second block is to be proceeded with at once; it will contain two lecture theatres, the library, a biological laboratory and other class rooms, and will cost about £5000. It has been necessary to erect the new buildings block by block, as the old buildings which are still in use have to be pulled down to provide the sites for the new buildings. On Monday, July 11th, the new buildings were opened by the Princess of Wales. The ceremony took place in the room which will be hereafter fitted up as the chemical laboratory. All of the buildings of the school of medicine were decorated with flags and flowers and very many spectators were present, including a large number of qualified medical women, former students of the school. All of them wore academic gowns and hoods. The Princess, who was accompanied by the Prince of Wales, was received by the dean of the school, Mrs. Garrett Anderson, M.D. Paris, who read an address of welcome, in which she said that since the school was started some 24 years ago the students had gained several gold medals at the London University and at the Royal University of Ireland. At present there were 170 students. Those who had passed out of the school and had obtained a medical qualification were engaged in responsible work as practitioners. Some were at the new hospital, others in workhouse infirmaries, asylums, and various provincial hospitals. Others were in India,

Digitized by Google

South Africa, China, and Australia. The block of laboratories which had just been erected, being part of the work of rebuilding the school, had cost between £9000 and £10,000. It had been paid for by donations, by a loan from the general funds of the school, and by the share allotted to the school from the Pfeiffer bequest. In memory of Mrs. Pfeiffer the wing would be named after her. After a prayer by the Bishop of London and an anthem by Madame Antoinette Sterling, the Prince of Wales, for the Princess, declared the building open. In the course of his speech he mentioned how fully the Princess of Wales and he sympathised with the desire of women to become qualified medical practitioners, and he thought that India and China offered an almost unlimited scope for the practice of medicine by women. It might have been thought, he continued, that medical men would resent the invasion of their province by women practitioners, but the presence of his friend, Sir William Broadbent, was sufficient proof that no such feeling existed. He had inspected several of the laboratories a few days before and he had been struck with the way in which they were fitted up. He had also paid a visit to the New Hospital for Women opened by the Princess of Wales about ten years ago, which was, he believed, officered entirely by former students of the school.

OPERATION IN MICROCEPHALY.

IN the December number of the *American Journal of Nervous and Mental Disease* Dr. W. W. Keen contributes some interesting remarks on the advisability of operation in cases of microcephaly. His views are based upon the work and writings of others, but also on an experience of 18 cases of his own in which he had operated. Of these the youngest patient was eighteen months old and the eldest six and a half years. Five died after operation and of the 13 that recovered 6 were slightly improved and 7 were not benefited. So that in Dr. Keen's experience the prospect of improvement is not great and the improvement which may take place is only slight. The conclusions, therefore, are that in a moderate number of selected cases of a medium degree of microcephaly death will ensue as a result of the operation and in a small number slight improvement will follow, but in the majority no result, good or bad, will result from the operation. He does not think that a child with an average-sized head is a suitable case for operation nor, on the other hand, does he think operation justifiable in cases in which the head is excessively small. In patients of more than seven years of age he is of opinion that improvement is not to be expected and in all cases after operation the greatest attention must be paid to developing the child's faculties by education.

ONLY A PAUPER AGAIN.

IN THE LANCET of June 25th we commented severely upon the disgraceful neglect of proper provision for the nursing of sick paupers at the St. Marylebone Infirmary Workhouse. England, it appears, is not alone in the crime of committing the most indefensible form of cruelty. There has recently been a Local Government Board inquiry into the administration of the Dumbarton Poorhouse which revealed a most scandalous state of things. The inquiry was undertaken at the request of the Old Kilpatrick Parish Council and the gentleman appointed to inquire was Mr. R. B. Barclay, who, curiously enough, is not only outside visiting officer for supervising outdoor relief but also has for the past twelve years acted as Inspector of Poorhouses and Poorhouse Hospitals, so that the Local Government Board in appointing Mr. Barclay set him to inquire into the efficacy of his own inspection, and we must compliment him warmly on the fact that he found that most of the charges formulated by the parish council were true. In his report upon the poorhouse hospital he mentions that the sanitary arrangements were defective; there were no fires in the wards at night; the nurses, an old woman aged seventy-three years and a younger woman aged forty years who is epileptic, sleep in the kitchen and can only be summoned at night by the patients knocking on the locked doors of the wards. The hospital dietary is the same as in the ordinary wards except when the medical officer orders special diet. It is satisfactory that Mr. Barclay considered that the governor and the matron did their best with the very limited material which they had at hand. Other portions of the report dealt with the administration of the poorhouse itself and many deficiencies were pointed out. The Old Kilpatrick Parish Council considered this report at a meeting held on May 9th and finally came to the conclusion that the Local Government Board should insist upon the House Committee resigning *en bloc*, also that the Local Government Board should be requested to at once make arrangements for carrying out the recommendations made in the report. It is true that the conditions in workhouses and workhouse infirmaries have improved greatly within the last forty years or so, but very much remains to be done. There is still not enough separation between the lazy loafer who enters a workhouse because he does not mean to do any work and the aged and the feeble who enter the same place on account of old age or sickness. The former class deserve no mercy and should be incontinently committed to prison and made to work. But the latter class are in every way pitiable and what they want is a rest house, not a workhouse. The difficulty of providing each class with its deserts ought not to be insuperable, but in the meantime such scandals as those upon which we have been commenting must not be allowed to recur.

MUMPS WITHOUT INFLAMMATION OF THE SALIVARY GLANDS.

IT is gradually becoming more and more evident that the only essential element of an infectious disease is the invasion of the body by a specific microbe. The resulting symptoms and lesions are indefinitely variable. Of late years, partly from clinical observations, but mainly from bacteriological researches, the limits of these variations have been considerably extended. Lesions once supposed to be so characteristic that they entered into the definition of the disease may be entirely absent. Thus typhoid fever is not necessarily enteric; there may be no intestinal lesions. The pneumococcus, the most usual cause of acute pneumonia and the presence of which in other tissues causes the so-called complications of that disease, may attack these tissues and exempt the lung, producing a primary pneumococcic arthritis, pericarditis, &c. At a recent meeting of the Société Médicale des Hôpitaux Dr. M. A. Béclère read a case which showed without doubt that mumps may manifest itself by orchitis without parotitis or inflammation of the other salivary glands. This has already been stated by M. Laveran and seems to be well known in France, but it does not appear to have been observed in this country, though Dr. Eustace Smith states that the orchitis may exceptionally appear before the parotitis. A boy, aged fifteen years, was suddenly seized with violent headache, pyrexia, and repeated vomiting. On the fifth day the right testicle became painful. On the following day he was seen by a distinguished surgeon who finding orchitis with predominating epididymitis thought, as there was no urethritis, that the case was one of acute tuberculous orchitis, although the temperature was 104° F. Dr. Béclère saw the boy on the eighth day. He ascertained that three of his school-fellows had mumps and diagnosed the orchitis accordingly. Resolution was complete on the

Digitized by Google

fourteenth day. All doubts as to the diagnosis were soon removed, for his two sisters had typical attacks of mumps. Dr. Béclère pointed out that the diagnosis should be made by the history of an epidemic, the sudden onset of the illness, and the interval of four or five days between the general symptoms and the orchitis. The diagnosis is of importance if only to enable the practitioner to warn the patient's friends that atrophy of the testicle sometimes results.

THE REPORT OF THE SELECT COMMITTEE OF THE HOUSE OF COMMONS ON PETROLEUM.

THE product of four years' labour has at length been placed upon the table of the House in the usual form of a blue-book report. The principal points in the report are that the committee recommend by a majority of one the raising of the flash-point to 100° F. Abel test; by a majority of 8 to 3 the regulation and construction of lamps; by a unanimous vote the regulation of storage and by a substantial majority the regulation of transport. Oddly enough, at the last sitting it was in the power of Mr. Collings and his friends to reverse the decision arrived at on June 24th. Two of the low-flash point partisans, however, refrained from voting and the chairman did not vote, and the report was finally adopted by a majority of one. It is unfortunate that an unanimous conclusion could not have been arrived at in accordance with the very great importance of the issue. We hope next week to deal fully with the report, copies of which have not been published up to the time of going to press.

GEOLOGICAL MODEL OF LONDON AND SUBURBS.[1]

A MAP of London and the surrounding country on a convenient scale of size, with the natural elevations of the ground shown in relief and the character of the superficial strata distinguished by colours, is a valuable means of conveying topographical information and Mr. Jordan is to be congratulated on the excellent manner in which his idea has been carried out. The district delineated by him extends from Finchley and Woodford on the north to Croydon and Orpington on the south, and from Barking and Chislehurst on the east to Hampton Court and Harrow on the west. The map is drawn on thin sheet metal embossed to represent the elevations and enamelled in eight different colours showing the nature of the ground. It has a handsome appearance and the black lines marking the various roads, streets, railways, &c., as well as the names of places, are as distinct as on a map printed on paper. The horizontal scale is 1 in. to the mile, and as it measures 15¾ in. from north to south and 20 in. from east to west the area included is obviously about 320 square miles. The vertical scale is 1 in. to 1000 ft., which is of course about five times as great as the horizontal scale, so that some of the steep inclines about Highgate and Muswell-hill have the appearance of being impracticable for any kind of wheeled vehicle without cable traction. The predominant geological formation is gravel and sand, which stretch across the map from south-west to north-east; London clay covers large tracts in the north-west and southern portions of the district; lower London tertiary deposits are found abundantly to the east of a line drawn from Croydon to Greenwich. The other formations shown are of less extent and consist of alluvium, brick earth, boulder clay, Bagshot sand, and chalk. Vertical sections of the various strata are represented on the frame, some of them being over 1000 ft. in depth. The map is provided with rings on the back by which it may be hung against the wall of a room like a picture. Mr. H. B. Woodward's memoir on the Soils and Subsoils of London and its Neighbourhood, reviewed in THE LANCET of Feb. 5th (page 372), may be advantageously consulted in connexion with the subjects of the map.

[1] By James B. Jordan. London: Edward Stanford. 1898. Price 15s.

THE PRINCE OF WALES'S HOSPITAL FUND FOR LONDON.

THE practical and delicate work of distributing the receipts of this Fund is now proceeding and by the kindness of Sir Savile Crossley, the honorary secretory of the Fund, we are able to tell our readers something of what is being done. The metropolitan area has been divided into four districts, North, South, East and West, the areas being as nearly as possible equal in the number of hospitals and the total number of beds. To define the boundaries of such areas was no simple matter. Each quarter has been assigned to a divisional sub-committee. Each sub-committee consists of five members, of whom two are thus far experts in hospital management that they are members of the medical profession, the other three being laymen, but men of business and interested in hospital work. One expert and one layman visit each hospital in the district and report upon it, and this is the work which has already been started; but it is considered undesirable until the work is complete to publish the names of the gentlemen who have so kindly undertaken the onerous task of serving on these sub-committees. It is hoped, however, that the names may be given later. At present the sub-committees are confining their visits and inquiries to those hospitals which applied for a grant in accordance with the advertisements inserted in the newspapers on May 17th and 24th, stating that all applications are required to be made by the end of June. The consideration of other claims is for the time deferred. Our readers are thus able to see that the General Council of the Prince of Wales's Hospital Fund for London have started on their task with a full sense of their responsibility; and in our opinion the method adopted for arriving at the real needs and merits of the charities which have applied to them for assistance is an excellent one. It should be thorough without being offensive and result in a proper allocation of the benefits to deserving institutions.

WATER GAS.

CARBON monoxide is an insidious poison, and since it is coming into increasing use, added in the form of water gas to coal gas, it is desirable that some control should be placed upon the public supply of gas so compounded. The gas derived exclusively from coal contains considerably over 5 per cent. of carbon monoxide, but of recent years this quantity in the gas supplied has very materially increased because at the gasworks it is now found expedient to enrich the gas by the addition of carburetted water gas. Water gas is a mixture of nearly equal proportions of carbon monoxide and hydrogen which serves as an excellent carrier of oil gas, the enriching mixture consisting of equal volumes of oil gas and water gas and being known as carburetted water gas. It is asserted that this step is necessary if the illuminating value of coal gas is to be maintained at the Parliamentary standard—namely, 16 candles. The supply of rich coal yielding a highly illuminating gas is said to have fallen short in recent years of the demands and thus the addition of carburetted water gas is adopted. The question as to whether this addition should be limited is at the present time occupying the attention of a Departmental Committee of the Home Office. We certainly are of opinion that some precise limit should be imposed, although hitherto we do not think any serious mischief has been done. Still without some definite system

Digitized by Google

of control mischief may be done, and as far as we know there is no law providing against the supply of pure carburetted water gas which would contain over 20 per cent. of deadly carbon monoxide. Coal gas is of course itself a poison and has been used successfully for criminal purposes, while cases of accidental poisoning from its use have not infrequently occurred. The danger would be greatly accentuated of course by a gas containing an increased proportion of carbon monoxide. Again, while carburetted water gas has a decided and distinct smell it is not so pronounced as coal gas, an important property of the latter which has undoubtedly sometimes prevented disaster. We do not suppose, however, that there would be any difficulty in endowing a gas for public supply with an unmistakeable smell. On reviewing the whole question, therefore, it is clear that some control must be placed upon the composition of the public gas-supply and that soon, before any serious charge can be laid at the door of the gas companies. The Public Control Committee of the London County Council has expressed its views to the Home Office, which are as follows:

(1) That considerable danger arises from the introduction of water gas in the process of the enrichment of coal gas; (2) that non-carburetted and non-odorised water gas should not be allowed to be used under any conditions, since it is devoid of smell which would give warning of any escape of the gas; (3) that 25 per cent. should be the *maximum* amount of water gas allowed to be introduced in the enrichment of coal gas, the proportion of water gas being ascertained by determining the amount of carbonic oxide in the enriched coal gas (coal gas enriched to this extent would correspond in poisonous character to the Dowson gas which is already in use for heating purposes and for gas engines, and would exclude the use of carburetted water gas); (4) that when it is proposed to supply poisonous enriched gas to houses and the interior of buildings a proper inspection be made of the service pipes by a responsible officer appointed by the local or other suitable authority, who should certify that the pipes are in a sound condition and that there is no escape of gas, and that the cost of such inspection be borne by the gas company.

We cordially agree with these suggestions and hope that the Government will soon see their way to embody them in a short Act providing for the control of the composition as well as for the quality of the public gas-supply.

THE DRAINAGE OF SWANAGE.

IN our issue of Sept. 18th, 1897, we commented upon a report by Dr. S. W. Wheaton upon the sanitary condition of Swanage. Swanage is one of those places which the Local Government Board thinks necessary to inspect very frequently, for its drainage is disgraceful. In 1893 the town council borrowed £6000 to make new sewers which should discharge into the sea below low-water mark. The sewers were made, but up to now they still discharge on the foreshore. The *Bournemouth Guardian* has been publishing some very plain-spoken articles about the neglect of the work and these articles have naturally excited the ire of some of the members of the urban district council, so a motion was moved and carried that notice of the council meetings should not in future be sent to the *Guardian*. On July 11th the council met as usual and a *Guardian* reporter attended but was requested to withdraw. During the discussion one of the members is reported as saying "that in the *Guardian* everything was drainage—and nothing else but drainage. He thought the council should request the papers to place as little as possible in their columns concerning the drainage as it did injury to the town." Another member is reported as saying "that those who gave up their time for the benefit of the people of Swanage were not prepared to be held up to ridicule by some snobs on newspapers." At the risk of incurring the latter speaker's displeasure we must say that if the drainage scheme is not pushed forward and the other gross insanitary defects pointed out by Dr. Wheaton removed "those who give up their time for the benefit of the people of Swanage" will have a rude awakening. Visitors will rightly keep away from the town, but the Local Government Board will not, neither will typhoid fever. We suppose the council are within their legal rights in asking the *Guardian* reporter to withdraw, but even if so it was the worst thing from their own point of view that they could have done.

THE HUXLEY LECTURE.

OUR readers will learn from an announcement which appears in our advertisement columns that Professor Virchow, of Berlin, has consented to deliver the forthcoming Huxley Lecture at the Charing-cross Hospital on Monday, Oct. 3rd, at 4 P.M. This lectureship was founded at the death of the late Professor Huxley out of a sum raised by the Medical School and its friends to commemorate the fact that Huxley received the whole of his medical education at Charing-cross. The lecture is a biennial one and the subject of that to be delivered by Professor Virchow is Recent Advances in Science and their Bearing on Medicine and Surgery. The first Huxley Lecture was delivered by Professor Michael Foster in October, 1896, and Professor Virchow's lecture on Oct. 3rd will be the second. The Charing-cross Medical School is to be congratulated on the honour which the most venerable and most distinguished of pathologists is willing to pay to the memory of perhaps the most honoured student of that school. It is now five years since Professor Virchow visited this country to deliver the Croonian Lecture for the Royal Society and those who took part in his reception on that occasion will not forget the interest which his visit excited or the cordial welcome which was everywhere extended to him. The Huxley Lecture will be delivered in English, of which language Professor Virchow is a master.

MR. BALFOUR ON MEDICAL RESEARCH.

ON July 13th the First Lord of the Treasury distributed the prizes to the successful students at Guy's Hospital. After the prize-giving he addressed his audience in a telling speech. Commencing by paying a warm tribute of esteem to the nobility of the medical profession, and having referred to his recent election as a governor of the hospital, Mr. Balfour proceeded to point out how science was necessarily getting more and more specialised and that therefore medical men and those whom they would have to treat were being gradually compelled more and more to rely upon those whose work was mainly research. He continued:—

"The man who would succeed in research, the man who, at all events, desires to devote himself to research, must not be asked to burden himself with other labours. He has upon his shoulders not merely what I may call the specialised work of his profession, but he must have a sympathetic and appreciative eye to everything which is going on in other departments of science, so that even where he cannot follow those other departments minutely he knows by the instinct of genius where to pick up those new discoveries which may help his own special branch of research. For men of that kind I think we require further endowment. I have all my life been on ardent believer in the cause which is often laughed at—the cause of the endowment of research. In that cause I most firmly believe, and I think there is no branch of knowledge in which it may find a more useful field of application than in that of advancing medical knowledge."

These are noble words, and we only hope that the speech of Mr. Balfour may be some indication of the mind of the Government, although we do not mean it to be implied that

Digitized by Google

he was speaking in any other than a private capacity. The British Government has hitherto been indifferent to the endowment of research. Everyone will remember Pitt's answer to the modest request that the Government would grant a few thousands for the purchase of the Hunterian collection: "We want the money to buy gunpowder," was the only reply. This was in 1793, but it is fair to say that in 1799 the Government did buy the collection for £15,000. Compared, however, with foreign countries Great Britain is sadly deficient in State-aided laboratories or scientific endowment of any kind. At the close of his speech Mr. Balfour implied that he looked to those who already subscribed for the pure medical and surgical work of a hospital to endow research. We ardently trust, however, that his presence at Guy's Hospital may prove the earnest of a Government grant for research in the future.

SYPHILIS OF THE STOMACH.

SYPHILITIC lesions of the stomach have been but seldom described. Possibly, as M. Dieulafoy has recently asserted, they are not so uncommon as is supposed, for when they come under clinical observation it is usually as ulcers of the stomach and the symptoms do not differ from those of ordinary ulcer. Gummata have been found at necropsies, but as a rule they produce symptoms during life only when they ulcerate. A case such as the following, published in *La France Médicale*, July 1st, 1898, by Dr. Dubuc, is very exceptional. In 1880 and 1881 he treated a man for primary and secondary syphilis and in 1884 for a tubercular syphilide on the forearm. In 1891 he detected in the epigastric region a large indurated plaque of the size of the palm of the hand, with a projection having the volume of a pigeon's egg. It was situated behind the abdominal wall and no doubt in the wall of the stomach. It was separated from the liver by a narrow resonant zone and was elevated by the pulsations of the aorta. The patient had wasted, digestion was slow and difficult, and there was pain in the affected region. Mercury and iodide of potassium were given; the plaque appreciably diminished in a week, and was found to have entirely disappeared when the patient was seen four months afterwards. M. Dieulafoy's advice to inquire for a syphilitic history in all cases of gastric ulcer and to treat accordingly is sound.

THE PROSPECTS OF NEW LEGISLATION ON POISONS AND FOOD.

WE must express our satisfaction with the steps which, as announced by Mr. Balfour in the House of Commons on Tuesday, the Government propose to take in regard to two measures in the progress of which we are interested. The Poisons Bill has been thrown over definitely and, in the words of Mr. Balfour, the Government have abandoned all hope of passing it into law. Last week we expressed the opinion that the Bill was unsatisfactory and not only so, but likely if passed to interfere with, if not to nullify, the good being done by the present Pharmacy Act. We take it that the Government found it expedient to drop this Bill on account of the opposition shown to it. It was certainly pushed through the House of Lords by the Duke of Devonshire with extraordinary rapidity. Indeed, it passed the House of Lords practically without discussion. As we said last week, if a really protective measure is to become law the Bill introduced by the Duke of Devonshire must be very seriously altered and amended. We receive, therefore, the announcement of Mr. Balfour with satisfaction and may now hope that a more satisfactory measure will be drafted in the future. It is hardly possible that the new Food and Drugs Bill will be passed this session, but at any rate it is to be introduced at an early date—probably next Tuesday. We believe that the new Bill is a very comprehensive measure, and it will, there is little doubt, give rise to considerable discussion. The terms, we believe, of its provisions are much in a line with those of the Bill introduced in January, 1897, which was dealt with at some length in a leading article in THE LANCET of March 6th, 1897. We should very much like to see it pass speedily, because we believe the Bill to be a good one and calculated to check the many fraudulent practices which now so artfully escape punishment under the present *régime*.

DEADLY ICE-CREAMS.

ANOTHER case is reported of a death presumably due to the eating of ice-creams. The victim was a child aged three years. The medical man in attendance deposed at the inquest that on the previous day he had seen two similar cases in the same street in Hoxton. Surely the authorities should do something in the matter. Is the liberty of unlicensed killing to continue indefinitely? There is proof, circumstantial, bacteriological, and positive, of the deadliness of the filthy "hokey-pokey" and it is high time that regulations were made with regard to its manufacture.

DR. CORNELIUS HERZ, whose death occurred at Bournemouth recently, was a medical man, but his place in science was won by his practical work in electricity. His death was due to angina pectoris and in its mode of onset sufficiently justified the opinion of the well-known English physicians who refused to take the responsibility of saying that he was in a fit state to appear at the Extradition Court.

THE Queen has sent a donation of £20 to the fund for the proposed children's wards in the Kensington Dispensary.

DR. LOMBE ATTHILL has been elected an Honorary Fellow of the Edinburgh Obstetrical Society.

A REPORT ON PELLAGRA IN TRANSYLVANIA.[1]

THE south-eastern part of the Carpathian Mountains forms the boundary between the kingdoms of Roumania and Hungary. Its slopes on both sides are inhabited by the Wallachs, now called Roumanians. They have the same habits and religion, the only difference being that the people on the northern side owe allegiance to Hungary, whilst those on the southern are subjects of the King of Roumania. They are supposed to be the descendants of the legionaries of ancient Rome who were stationed in these parts in the time of the Emperor Trajan and his successors. These people are very poor and live under highly insanitary conditions. Pellagra, which, as is generally known, prevails in certain districts of Italy as an endemic disease, has apparently been unknown hitherto in these parts, at any rate as far as the authorities and the medical profession generally are concerned, but it has recently attracted the notice of sanitarians in the shape of an endemic outbreak. To inquire into the circumstances of this outbreak the Hungarian Government appointed a Commission, consisting of Dr. Niedermann, Dr. Konrád, and Dr. Farkas, which has just presented its preliminary report to the Minister of the Interior at Budapest. The Commission commenced its labours in April last by visiting the villages where the disease was known to prevail, and at the termination of this inquiry it made the preliminary report referred to above from which we glean the following.

It appears that about fifteen years ago Dr. Takách, of the county of Kövár, noticed in his neighbourhood some

[1] **A Pellagra: Niedermann Gyula tr., Konrád Jenö tr. és Farkas Jenö tr. jelentése az erdélyl megyékben fellépett pellagra megbetegedésekről. (Pellagra: A Report of Dr. Gyula Niedermann, Dr. Jenö Konrád and Dr. Jenö Farkas on Pellagra Cases which occurred in some of the Counties of Transylvania.)**

Digitized by Google

suspicious cases of skin disease which he named pellagra and described it as such in the medical journals; but owing to doubts expressed by a dermatologist at Budapest as to the correctness of the diagnosis the subject was dropped. Last year, at the International Plague Conference in Venice, the Hungarian delegate, Dr. Chyzer, met Dr. Felix, a delegate of Roumania, and learning from him that pellagra frequently occurs on the southern slopes of the Carpathians he was induced to visit the provincial hospital of Venice and to study some of the cases of pellagra there. On his return to Budapest he gave directions to the chief physician at Kolosvár and to the physician in charge of the lunatic asylum in that city to pay special attention to cases of pellagra, and at the same time he entered into correspondence with Dr. Felix of Bucharest and with several medical practitioners in Transylvania. Dr. Takách was the first to send a patient suffering from pellagra from the town of Somkút to the clinique at Kolosvár; this was on April 19th last. Dr. Lechner, Professor in the University of that city, confirmed the diagnosis and submitted the case to the Commission. The following, taken from their report, may serve as a fair type of cases described.

A married man, aged twenty-six years, of feeble constitution, a farmer, was born of healthy parents in the county of Szathmár. When seven years old his foot was injured by a thorn and periostitis ensued. The part became considerably swollen and he was for a long time under treatment in a hospital, where he underwent an operation, but the suppuration, owing to diseased bones, still continued. At the age of eighteen years he married. His habits were temperate, his ordinary diet consisting of porridge made of Indian corn, wheat-bread, bacon, eggs and milk. Since last autumn his diet has consisted exclusively of Indian corn mixed with wheat-flower. In the spring of 1897 there appeared an affection on the skin at the back of his hands. He became excited, spoke and acted confusedly, and walked about aimlessly, stopping people in the street and saying that he was in search of a wife, although he was already married. By the end of spring the skin disease had disappeared and his brain symptoms had improved, but it was nevertheless thought that he still suffered from hallucinations. In March, 1898, his hands, face, and neck became swollen and erythematous, and his skin grew fissured and knotty and covered with scales and was peeling. He again became excited and spoke and acted in a confused manner and, his agitation increasing, he ran away from home and made attacks on men and on animals. The patient's restlessness subsided on his admission into the hospital, but he became apathetic and stupid, had illusions, saw spectra, heard strange sounds, and refused to take food.

After establishing the diagnosis of the above case as pellagra, other cases of the disease were recognised at the clinique of the University of Kolosvár by Dr. Purjesz and Dr. Marsalko, 11 of which were seen by the Commissioners. On May 20th, 1898, they visited the village of Nagykalota, where in former years the food of the inhabitants was wheat and rye, but this year it was Indian corn. A miller there stated that this year no pure wheat was ground in his mill, although formerly he had a good deal to grind, and he added that "pigs fed better formerly than men do to-day." Last summer many people suffered from malaria and still continue to do so to a certain extent. The village rates amount to 106 per cent. of the ordinary taxes. The Commissioners also examined numerous cases in sixteen different villages with the same result. The symptoms were of the type described above. The disease may be said to be the result of insufficient nourishment aggravated by bad hygienic conditions and by malaria. No cases of pellagra could be detected where the people had good and sufficient food.

The Commissioners conclude their report as follows: "From the above examinations of many cases we arrived at the conclusion that under similar dietetic and hygienic conditions pellagra in an endemic form will be found in other parts of the country. Before submitting a final report we may place our opinion on record that the exclusive use of Indian corn as food is the ultimate cause of pellagra and the nutriment of the people in those places was this year even worse than usual, because (1) the crop last year was of an inferior quality; (2) for the last three years there prevailed a murrain among the flocks, particularly among the pigs; and (3) the flocks of sheep have likewise suffered severely, the consequence being that the people have had no animal food during the winter. All this was aggravated by the continuous rains of last year which produced malaria."

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

THE twenty-ninth sitting of the Royal Commissioners was held at the Guildhall, Westminster, on Monday, July 11th. The only Commissioners present were the Chairman (Lord Llandaff), Major-General Scott, Mr. de Bock Porter, and Mr. Robert Lewis. The first part of the sitting was occupied by taking the evidence of Mr. Andrew Johnston (chairman of the Essex County Council), Mr. W. B. Whittingham (chairman of the Water-supply Committee of the Essex County Council), Mr. William Ivey (Mayor of West Ham), Mr. Frederick Ernest Harris (treasurer of the borough of West Ham), Mr. W. K. Marriott (chairman of the Barking Urban District Council), and Mr. Alfred Plant (accountant to the East Ham District Council). After the adjournment for luncheon evidence was given by Mr. T. L. Knight (chairman of the East Ham Urban District Council) and by Mr. C. G. Musgrave (chairman of the Leyton Urban District Council); and Sir John Evans, K.C.B. (vice-chairman of the Hertfordshire County Council), put in a statement on behalf of the county which he represented and was examined at some length.

Mr. JOHNSTON, in answer to the CHAIRMAN, said that the population of the geographical county of Essex according to the census of 1891 was 785,445 and that of the administrative county 578,471. The county borough of West Ham was entirely within the limits of supply of the East London Waterworks Company. The county council of Essex and the borough of West Ham had acted in concert with a view to opposing the London County Council's Water Transfer Bills. They were, however, willing to come to an arrangement with the London County Council on certain conditions and an agreement was drawn up last year but it was never "signed and sealed." The arrangement was, briefly, that the London County Council should hand over to the Essex authorities the supply and distribution of water within that county. In the county of Essex there were besides the county borough of West Ham ten separate local authorities which were either wholly or partially supplied by the East London Waterworks Company. These districts were Walthamstow, Leyton, Wanstead, East Ham, Woodford, Buckhurst-hill, Chingford, Waltham Holy Cross, Ilford, and the Epping Rural District Council area (Loughton and Chigwell). The Barking Local Authority was also within the company's limits of area and might at any time require a supply of water. The witness thought it was not expedient that ten or more separate water authorities should be formed within the Essex district of supply of the East London Waterworks Company, and that might happen if the powers contained in a clause of the East London Waterworks (Purchase) Bill introduced by the London County Council last year had received Parliamentary sanction. Most of the districts of the local authorities which had been mentioned are supplied by mains passing through one or more other sanitary districts, and had one or more of the local authorities availed themselves of the powers proposed by the London County Council's Bill and undertaken the distribution of water in their respective districts the arrangements would have become very complicated, and if the various parts of the undertaking became vested in a number of different local authorities they would necessarily have to employ additional officers and servants in each district, and the result would be a very heavy expense which would fall directly on the ratepayers.

In answer to Mr. DE BOCK PORTER the witness said that the Essex County Council was not anxious to become the water authority, and they feared that a change from the present arrangement would have the effect of making them pay more for their water. The gross charge for water supplied by the East London Waterworks Company given on an average of six years had been 4·21*d.* per 1000 gallons and the average cost throughout the whole of the London water companies' area had been over 6·97*d.* The witness thought that had the undertakings been purchased by the London County Council they might have tried to charge the Essex district the average price charged for water over the whole of the metropolitan area of supply and in his opinion the East London authorities would be at a disadvantage either in the case of negotiations or

Digitized by Google

arbitration if they had any dispute with regard to charges with so rich and so powerful a body as the London County Council and in his opinion they were in danger of having to pay as much as 66 per cent. more for their water than they do at present. In the case of purchase of the metropolitan water companies' undertakings by the London County Council the Essex authorities had drawn up a statement of their opinions which were that—

1. The London County Council should be subject to all the liabilities of the East London Waterworks Company. 2. That a provision should be made enabling the Essex County Council to promote and pay the costs of promoting a Bill to constitute an Essex water authority (with or without the county borough of West Ham), and to authorise such water authority to purchase, on terms to be settled by arbitration, such portion of the undertaking of the East London Company which by the Act might become vested in the London County Council as might be necessary for the purpose of a supply of water both as regards present and future needs within their district. 3. That the said water authority might purchase the Essex portion on the same terms as the London County Council might acquire the whole undertaking of the company. 4. That the Essex County Council or the water authority might at any time within two years from the passing of the Act purchase the Essex portion. 5. That until an Essex water authority were formed the consumers within the Essex district should not be charged a higher rate for the supply of water than they then paid.

The Essex County Council had also passed the following resolutions in reference to their policy on the water question. On April 7th, 1896, the following resolution was passed:—

That the council have considered the Metropolitan Counties Water Board Bill and the proposed resolutions submitted by the Chairman of the Surrey County Council. That they find some provision is made in the Bill for the representation on the proposed water board of the districts outside the county of London, though leaving the outer districts in a minority, but at this stage they are not prepared to offer other comment on the Bill than the following: That a clause be introduced protecting the outside districts from any possible liability to contribute to the cost of bringing water to London from a great distance without the consent of their representatives, inasmuch as the outer districts have abundant sources of supply for themselves within their own areas which they should have the right to retain.

And again on Jan. 5th the following resolution was passed:—

That the President of the Local Government Board having asked for a formal statement of the views of the council as to proposed legislation in the matter of metropolitan water-supply a reply be sent as follows: (*a*) That if the metropolitan water area within the county can be assured of acquiring an adequate proportion of the sources of supply now used by the East London Water Company within such area a separate water authority be formed for such area, combined, if possible, with the county borough of West Ham, otherwise the Council would prefer representation on a general metropolitan water-trust. (*b*) That in any water-trust Bill a clause should be introduced protecting the outside districts from any possible liability to contribute to the cost of bringing water to London from a great distance without the consent of their representatives, inasmuch as the outer districts have abundant sources of supply for themselves within their own area which they should have the right to retain.

In answer to the CHAIRMAN the witness said that the parts of Essex not supplied by the East London Waterworks Company were partly supplied by the South Essex Water Company and by the Essex and Hertfordshire Water Company. In rural districts the water of "old horse ponds" was still used. The witness said that as far as he was concerned he was satisfied with the water supplied by the East London Waterworks Company.

Mr. W. B. WHITTINGHAM, in answer to the CHAIRMAN, said that complaints had been made with regard to the inadequacy of the supply by the East London Waterworks Company during periods of drought and of frost. If the London water companies' undertakings were purchased he thought the control should be vested in the Essex County Council.

Mr. WILLIAM IVEY, in answer to the CHAIRMAN, said that the county borough of West Ham was joined to the metropolis to the east of the River Lee and was divided from it by that river. The population of the borough was growing very quickly. Thus in the year 1851 the population was 18,807; in 1861, 37,639; in 1871, 63,969; in 1881, 128,953; in 1891, 204,903; and in 1897, 273,662. The borough contained a large number of business premises. The works of the Great Eastern Railway Company, the whole of the Victoria Docks, and part of the Albert Docks were within the borough. There were also large sugar, soap, and candle factories. The existence of all these factories depended on a constant supply of water. In the years 1894, 1895, and 1896 there was considerable dissatisfaction in the borough because of the dearth of the domestic water-supply, and for a great part of the time the borough was either without water altogether or on a very short supply. The witness considered that the River Lee was the natural watershed for the supply of West Ham, and if there was any amalgamation of the water companies the town council thought that a proper provision should be made for districts beyond the metropolitan area. The witness said that he believed that the East London Water Company had taken measures to prevent any repetition of the deficiency of the water-supply and subject to the question of the adjustment of the rating for water purposes and subject also to the application of the Water-rate Definition Act of 1855 to the West Ham district he did not think there was any reason why matters should not remain as they are at present. In the case of purchase of the East London Waterworks' undertakings he thought that looking at the magnitude of the area, the number of the population, and the vastness of their interests in the question, it would be most desirable that the Government itself should deal with the matter. But, failing that, if the water undertakings were acquired in any other way the corporation thought that they ought to have powers and privileges conferred upon them similar to those which had been arranged between the London County Council and the Essex County Council in case of the purchase of the undertakings by the former body. The matters which had not been satisfactory in the past were (1) that there had not been a constant supply; (2) that the supply had been insufficient in quantity; and (3) that the charges for water-rents were not fairly made. The charges had been levied on the "annual value," not on the "net rateable value." The question as to the legality of the charges had, however, not been raised in a court of law.

Mr. FREDERICK ERNEST HARRIS, treasurer of the county borough of West Ham, said that the people of West Ham had a distinct grievance against the East London Waterworks Company with regard to the charges levied for water-rents. By the Water Rate Definition Act of 1885 the words "annual value of the tenements supplied with water" are defined as follows: "The words 'the annual value of the tenement supplied with water,' in the 68th Section of the Waterworks Clauses Act, 1847, shall within the unions and parishes to which the Valuation of Property (Metropolis) Act, 1869, extends, mean the rateable value as settled from time to time by the local authority as duly constituted." West Ham being outside the metropolis the words "annual value" are not defined by statute, and the East London Waterworks Company themselves determine what is the "annual value" and the water consumer, if aggrieved by the company's decision, has either to pay or to appeal to two justices. The practical result of the present state of things is that the company arbitrarily prescribe the charges for water and have adopted scales of charges which purport to represent the statutory charge of 5 per cent. upon the "annual value" and no information is given to the water consumer as to how the East London Waterworks Company's "valuation" is made. The witness had compared the rateable values as appearing in the ratebooks of the borough and found that the company's charges in West Ham were considerably higher than those which obtained in London. The witness had prepared two tables, one showing the rates charged in the case of cottages in which the landlords paid the rates and taxes, the other in the case of houses in which the tenant paid both rates and taxes. These tables showed that the amount of water rent charged in West Ham was higher than the water rent charged in London. For example, in the case of a cottage for which the rent was 8*s.* a week the water rent charged in West Ham was 12*s.* 6*d.*, and in London 11*s.*, the difference being 13½ per cent. In the case of a house of the rental of £30 a year in which the tenant paid the rates and taxes the water rent charged in West Ham was 26*s.* and in London 24*s.*, the difference in this case being 8½ per cent.

In answer to the CHAIRMAN the witness said there was no reason to justify this excessive charge on the part of the East London Waterworks Company.

Mr. W. K. MARRIOTT, chairman of the Barking Urban District Council, said that the whole of the district which he represented was in the area of supply of the East London Waterworks Company, but that company did not at present supply any part of it. The district was also within the Parliamentary area of the South Essex Waterworks Company. The population of that district was over 20,000. The Barking District Council were of opinion that in the event of the East London Waterworks Company being acquired by the London County Council a water trust should be formed composed of representatives from the various districts affected. The Barking District Council, however, did not agree to the proposal made by the Essex County Council that that body should be constituted the

Digitized by Google

Essex water authority representing the part of Essex within the East London Waterworks Company's limits of supply. The Council were of opinion that an authority constituted by the Essex County Council would not fairly represent the urban area of the district and they therefore submitted that if a water authority were formed it should be composed of persons representing the consumers directly and should be a popularly elected administrative body, and they suggested that the members should be elected from the several districts interested in proportion either to the population or to the rateable value of the districts supplied. If it were decided to allow the local authorities to obtain a sufficient water-supply for their own requirements the council were prepared to obtain such supply or to purchase water in bulk.

In answer to Mr. ROBERT LEWIS the witness said that the South Essex Waterworks Company obtained part of their supply from a well at Grays. The water supplied was all well water.

Mr. ALFRED PLANT, accountant to the East Ham Urban District Counncil, in answer to the CHAIRMAN said that the district of East Ham joined the county borough of West Ham. It was in the area supplied by the East London Waterworks Company. The population, which in 1891 was 32,713, was now estimated at 70,000. The area of the district was 3266 acres and the number of houses 14,500. The requirements of the district were similar to those of the county borough of West Ham. The area of supply of the East London Waterworks Company was confined in this direction to the districts immediately adjoining the metropolis, and the East Ham District Council were in favour of a joint Water Trust being formed for that part of Essex which was within the metropolitan area of water-supply, but they thought that the trust should be distinct from the London County Council. With regard to the difference of the charges of the East London Water Company in their metropolitan and extra-metropolitan districts tables were handed in showing that the charges made in East Ham were greater than those made in the case of similar cottages and houses within the metropolitan area.

Mr. C. G. MUSGRAVE, chairman of the Leyton Urban District Council, in answer to the CHAIRMAN, said that the district which he represented adjoined the metropolis and West Ham and was separated from the former by the river Lee. The whole of the district was within the area of supply by the East London Waterworks Company. The population of the district was nearly 90,000, comprised an area of 2491 acres, and contained about 15,500 houses. In the opinion of the Leyton UrbanDistrict Council it would not be possible for the Essex County Council to fairly represent them with regard to management of their water-supply. Should a new water authority be constituted the council were of opinion that—

1. Such authority should be constituted of persons directly representing the consumers. 2. That the supply of water should be directed by a popularly elected administrative body. That, in the event of Leyton being able to obtain a supply sufficient for its own purposes, the council would be prepared to acquire such supply, or as the supply is within the district of Leyton the council would be prepared to purchase water in bulk at cost price and distribute. 3. That in the event of Leyton being unable to obtain such supply limited to its own district a body should be elected from the various districts for which such supply is required in proportion to population of the districts supplied.

The witness said that his district suffered in the same way as West Ham from the overcharges of the East London Waterworks Company. They had also to complain that the supply was not constant. Last year no water could be obtained in the case of a fire. The East London Waterworks Company's officers had suggested that the fire brigade did not know their duty. The witness was of opinion that the fire brigade was an extremely efficient one and that there was no water available at the time of the fire.

Sir JOHN EVANS, K.C.B., in answer to the CHAIRMAN, said that he was vice-chairman of the Hertfordshire County Council. He had been desired by the Parliamentary Committee of the council to lay before the Commissioners a statement as to the best method of dealing with the question of the water-supply in the interests not only of the County of London but also of the outside areas. His statement dealt with the questions of the advisability of purchase or control, as to how control might affect the question of the quality and the quantity of the water supplied and also its effect on the charges. Purchase and control were considered as they affected the outside areas. In addition to this he had dealt with the question as to what additional powers of control were needed, as to the control of the abstraction of undergound water, and finally he made suggestions as to a new Waterworks Clauses Act. There were also notes on the existing acts for the control of the water supply in the metropolitan water area.

In answer to the CHAIRMAN the witness gave evidence with regard to the effect of pumping by the New River Company. In the opinion of the witness the effect of the uncontrolled pumping by the New River Company had been (1) that wells in Ware in summer are frequently pumped down; (2) that the springs and streams in the neighbourhood of the Amwell Marsh and Amwell Hill pumping stations are pumped dry by those wells when working; (3) that the water which stands in the ditches and ponds in the Lee Valley is affected by the pumping from the companies' wells; (4) that the well at Haileybury College is pumped down; (5) that the well at Beaumont Manor was pumped dry; (6) that the Barnet Water Company find the water in their well falling off yearly; (7) that the Cheshunt District Council's well has given out; (8) that the flow of the Ash, Rib, Quin and Beane tributaries of the Lee has fallen off; and (9) that the flow of the River Lee has been insufficient for the East London Company. The witness thought that no well ought to be sunk by a water company except under the authority of Parliament contained in a special Act. In his opinion an Act ought to be passed which provided that all companies proposing to construct and obtain their supplies from wells should be under an obligation to afford supplies of water to those in the neighbourhood of the proposed wells whose water-supply might be affected by pumping from them. He thought also that companies ought to be controlled by being compelled to afford a sufficient supply of water at a reasonable rate, so that the water consumers might get the benefit accruing to the companies by reason of the practical monopolies which had been conferred on them and he suggested as the lines upon which a solution of the present difficulties might be found: (1) a careful reconsideration of the existing powers to charge for water which are in the hands of the companies with a view to ascertaining whether those powers might be modified in such a way as to secure lower water charges and uniformity of charge over the whole of the metropolitan water area; and (2) a reconsideration of the limitations under which the companies are now required to issue their capital and the amount of dividends which they may pay.

The next sitting will be held on Monday next, July 18th, at the Guildhall, Westminster.

MEDICAL REFORM AT LEWISHAM.

A WELL-ATTENDED meeting of the medical profession of Lewisham and the neighbourhood was held at the Infirmary, Lewisham, on July 6th to hear an address from Mr. R. B. Anderson, as representative of the Corporate and Medical Reform Association, Limited, on "Practical Measures for the Prompt Attainment of Corporate and Medical Reform and for the Maintenance of the Rights and Promotion of the Honour and the Interests of the Medical Profession." Dr. F. S. Toogood, medical superintendent of the Infirmary, presided.

Mr. ANDERSON'S address dealt with what he considered to be the principal evils and abuses which afflict and injure the profession and the public, and showed them to be due to the exclusion of the body of the profession from influence in and control of the corporations, a position which he said could be remedied only by combined action of the profession and the public for obtaining from the State facilities for the self-government of the profession.

It was moved from the chair, seconded by Mr. F. S. BARNETT (Lewisham), and carried unanimously:—

That this meeting of registered medical practitioners of Lewisham and the neighbourhood, constituents of various medical corporations, supports the principles and policy of the Corporate and Medical Reform Association, Limited, and will coöperate collectively and individually by every constitutional means in promoting its measures, particularly combined action of the medical profession and the public to effect the reforms desired.

It was then moved by Mr. F. S. BARNETT, seconded by Dr. J. P. HENRY, and carried *nem. con.*:—

That a provisional committee of members of or joining the association be appointed, with power to add to its numbers, to act with the association in approaching public men and public bodies, medical and

Digitized by Google

lay, to invite coöperation in the south-east district of London and throughout the county of Kent in organising a county of Kent branch.

A local committee was then formed with Mr. F. S. Barnett (Lewisham) as local hon. sec.

The meeting terminated with votes of thanks to Mr. Anderson and to Dr. Toogood for receiving the meeting and presiding.

MEDICAL REFEREES UNDER THE WORKMEN'S COMPENSATION ACT.

THE following is a list of medical referees who have been appointed by the Secretary of State for England and Wales for certain county court circuits in respect of which the arrangements are for the present complete :—

Circuit No. 1.—Dr. George Hare Philipson, Dr. Frederick Page, and Dr. George Halliburton Hume, Newcastle-on-Tyne; Mr. Charles Clarke Burman, Alnwick; and Dr. William Bertie Mackay, Berwick-upon-Tweed.

Circuit No. 2.—Dr. Selby Wetherell Plummer, Durham; Mr. Thomas Alexander McCullagh, Bishop Auckland; Dr. James Murphy, Sunderland; Dr. Robert Anderson, Seaton Delaval; Dr. William Mearns, Gateshead; and Dr. Frederick Hughes Morison, West Hartlepool.

Circuit No. 4.—Dr. James Arthur Rigby and Dr. Edwin Moore, Preston; Mr. Arthur Stanley Barling, Lancaster; Dr. Leonard Greenham Star Molloy, Blackpool; Dr. John Michael Harding Martin, Blackburn; and Mr Oswald Samuel Wraith, Darwen.

Circuit No. 6.—Mr. George Gibson Hamilton and Mr. Joseph D. Crawford, Liverpool; Mr. Robert Meredith Littler, Southport; and Mr. Charles Stuart Pethick, Woolton, Liverpool.

Circuit No. 7.—Dr. George Harry Cooke, St. Helens; Mr. Damer Harrisson, Liverpool; and Mr. Joseph Collier and Mr. Herbert Lund, Manchester.

Circuit No. 11.—Dr. James Mackenzie, Burnley; Mr. William Henry Ellis, J.P., Shipley; and Mr. William Henry Horrocks, jun., and Dr. Henry Johnstone Campbell, Bradford, Yorks.

Circuit No. 12.—Dr. Thomas Michael Dolan, Dr. John Crossley Wright, and Dr. Alfred Mantle, Halifax; and Dr. Thomas Kilner Clarke and Mr. Peter Mac Gregor, Huddersfield.

Circuit No. 17.—Dr. William Arthur Carline and Mr. William John Cant, Lincoln; Dr. George Skelton Stephenson, Grimsby; and Dr. Arthur Tuxford, Boston.

Circuit No. 20.—Mr. Claude Douglas, Mr. Frank Montague Pope, and Dr. Thomas William Gordon Kelly, Leicester; Mr. Joseph Balm Pike, Loughborough; and Dr. William Newman, Stamford.

Circuit No. 21.—Mr. Harry Gilbert Barling and Dr. William Turberville Farncombe, Birmingham.

Circuit No. 23.—Mr. Henry Hammond Smith, Stourbridge; and Mr. John Lionel Stretton, Kidderminster.

Circuit No. 24.—Dr. William Taylor and Dr. Charles Tanfield Vachell, Cardiff; Mr. Octavius Edward Bulmer Marsh and Dr. Samuel Hamilton, Newport, Mon.; Mr. W. Edwin Williams, Abertillery, Mon.; and Dr. William Dyne Steel, Abergavenny.

Circuit No. 31.—Dr. James Fenton Stamper, Pembroke Dock; and Mr. Evan Evans and Mr. David James Williams, Llanelly.

Circuit No. 33.—Dr. Michael Beverley and Dr. Hamilton Ashley Ballance, Norwich.

Circuit No. 35.—Mr. Walter Gifford Nash and Mr. Edward Colby Sharpin, Bedford; and Mr. George Borthwick Mead, Cambridge.

Circuit No. 42.—Mr. James Berry, 60, Welbeck-street, Cavendish-square, W.; and Mr. William Bruce Clarke, 51, Harley-street, W.

Circuit No. 43.—Mr. Christopher Heath, 36, Cavendish-square, W.; and Dr. Herbert Campbell Thomson, 34, Queen Anne-street, W.

City of London.—Dr. William Murray Leslie, 23, Fenchurch-street, E.C.

METROPOLITAN HOSPITAL SUNDAY FUND.

THE following were among the principal amounts received at the Mansion House up to Wednesday last in aid of this Fund. The total now amounts to £37,000 :—

	£	s.	d.
St. Mary Abbotts Kensington :— Parish Church, £330 9s. 4d.; St. Paul, Vicarage Gardens, £154 5s. 0d.; Christ Church, Victoria-road, £99 10s. 3d.	584	4	7
The Very Rev. The Chief Rabbi, from London Synagogues, including: Great Synagogue, £260 10s. 2d.; New West End, £113 7s. 6d.; Bayswater, £88 7s. 0d.; Central, £77; Hampstead, £55 19s. 2d.; St. John's Wood, £37 9s.; North London, £31 12s. 6d.; Maiden-lane, £23 2s.; Dalston, £20 9s	855	18	9
Conference Hall, Mildmay-park	23	16	7
St. Thomas, Regent-street	20	0	5
Waltham Abbey Parish Church	24	3	4
Mr. W. Mann Cross, C.C.	20	0	0
Trinity Church, Hampstead	74	10	4
St. Andrew, Whitehall-park, N.	29	8	2
St. Luke, Westbourne-park...	42	6	10
St. James, Hatcham	75	9	3
All Saints, Camberwell	26	17	6
Chiswick Parish Church	28	13	9
Christ Church, Beckenham...	38	16	1
All Saints, Hatcham	21	2	5
St. Alphege, Greenwich	28	3	9
St. Luke, Redcliffe-square	51	6	5
St. Mary Magdalen, Munster-square	24	2	9
All Saints, St. John's Wood	21	12	6
All Saints, Child's Hill	21	14	9

Public Health and Poor Law.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Birmingham Sanitary District.—Dr. Alfred Hill is, in his twenty-fifth annual report, in no sense enthusiastic as to the sanitary progress of the city of Birmingham—that city which has ere now been held up as a pattern of municipal administration. The general death-rate is not, Dr. Hill considers, at all what it should be in relation to that of the other large towns, in spite of the fact that at one time the sanitary activity of the corporation led to a very marked diminution in the mortality. This is well shown by the following figures :—

	Average death-rate per 1000.
Five years 1873–77	24·8
,, ,, 1878–82	21·6
,, ,, 1883–87	20·7
,, ,, 1888–92	20·0*
,, ,, 1893–97	20·2*

* Enlarged city.

In 1873 Dr. Hill was appointed medical officer of health, and it is to the sanitary progress which took place in the decade following the appointment that this reduction in the death-rate is probably in large part due. During the past fifteen years, however, despite the extension of the city boundaries, there has been no reduction in the death-rate, and Dr. Hill refuses altogether to accept the position that no further reduction can be effected. He points out in opposition to this view that if other large towns can have death-rates below 20 per 1000 he sees no reason why Birmingham should not do the same. When, for instance, the last quinquennium is compared with the preceding decennium it is found that Blackburn has reduced its death-rate 4, Huddersfield 4, Halifax 3·8, Cardiff 3·8, Oldham 3·7, Preston 3·4, and Manchester 3·3 per 1000, while Birmingham has been practically at a standstill. If the mortality of Birmingham is to be reduced, it is essential, Dr. Hill thinks, to continue the improvements which were followed by such good results after he first took office. The sewers should be thoroughly examined as to their soundness, courts and terraces should be paved, pan-privies should be done away with, and the water-carriage system of excrement disposal generally adopted; scavenging of refuse should be improved and more air-space about dwellings insisted upon. The isolation hospital accommodation of Birmingham is, too, not what it should be, and those who do not already know it will be very surprised to hear that there is no provision either for diphtheria or enteric fever. In reference to this latter disease we notice that as a matter of precaution against the specific contamination of the public water-supply Dr. Hill wrote to every medical officer of health having jurisdiction in the watersheds from which the supply is drawn requesting to be informed of any cases of enteric fever which might occur, and in addition to this it was determined to make monthly bacteriological examinations of water taken from each of the three zones of supply. Diarrhœal diseases exacted an enormous toll in Birmingham during 1897, no less than 1444 deaths having been attributed thereto. Of this number as many as 1150 occurred during the third quarter of the year, and as regards age distribution 1074 were under two years of age and 930 under one year. Into the circumstances connected with a large number of these deaths Dr. Hill has gone very carefully and he found that overcrowding and insanitary yards and privies largely obtained; in fact, his observations have led him to agree entirely with the late Dr. Ballard as to the influence of fouled soil and accumulations of excreta and refuse. There are, we are told, still 30,000 pan-privies in Birmingham, and it is easy to understand that as long as these remain in existence no great progress is likely to be made. With regard to ensuring the free dilution of polluted air among and within dwellings, a point upon which Dr. Ballard insisted so strongly, Dr. Hill advises that steps be taken to reduce the density of the buildings in the older parts of the city. He thinks that a great deal may be done by pulling down under the Housing of the Working

Digitized by Google

Classes Act such buildings as obstruct ventilation and he is inclined to advocate a general adoption of this practice as being on the whole of more use—or perhaps we should say as being more practicable—than dealing wholesale with insanitary areas. There is certainly a great deal to be said for this view.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6509 births and 3154 deaths were registered during the week ending July 9th. The annual rate of mortality in these towns, which had been 15·1 and 14·9 per 1000 in the two preceding weeks, further declined last week to 14·7. In London the rate was 14·3 per 1000, while it averaged 14·9 in the thirty-two provincial towns. The lowest death-rates in these towns were 9·4 in Cardiff, 9·7 in Huddersfield, 10·3 in Brighton, and 10·9 in Burnley; the highest rates were 17·9 in Plymouth, 18·1 in Gateshead, 20·3 in Newcastle-upon-Tyne, and 21·4 in Sunderland. The 3154 deaths in these towns included 330 which were referred to the principal zymotic diseases, against 301 and 343 in the two preceding weeks; of these, 99 resulted from whooping-cough, 68 from diarrhœa, 67 from measles, 48 from diphtheria, 25 from scarlet fever, and 22 from "fever" (principally enteric). No fatal case of any of these diseases occurred last week in Birkenhead or in Burnley; in the other towns they caused the lowest death-rates in Brighton, Blackburn, and Preston, and the highest rates in Gateshead, Sunderland, Newcastle-upon-Tyne, and Plymouth. The greatest mortality from measles occurred in Croydon, Plymouth, and Gateshead; from scarlet fever in Gateshead; from whooping-cough in Bolton, Oldham, Salford, Sunderland, and Newcastle-upon-Tyne; and from "fever" in Swansea. The 48 deaths from diphtheria included 27 in London, 6 in Leeds, and 3 in West Ham. One fatal case of small-pox was registered in Liverpool, but not one in any other of the thirty-three large towns; and no small-pox patients were under treatment during last week in any of the Metropolitan Asylum Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital was 2250 on Saturday last, July 9th, against 2194, 2238 and 2205 at the end of the three preceding weeks; 237 new cases were admitted during the week, against 230, 231, and 204 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 171 and 162 in the two preceding weeks, further declined to 160 last week, and were 25 below the corrected average. The causes of 42, or 1·3 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Bradford, Leeds, Hull, and in twelve other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Manchester, and Burnley.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·5 and 21·1 per 1000 in the two preceding weeks, declined again to 20·0 during the week ending July 9th, but exceeded by 5·3 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 14·3 in Leith and 14·5 in Paisley, to 25·3 in Dundee and 27·2 in Perth. The 603 deaths in these towns included 36 which were referred to measles, 27 to diarrhœa, 21 to whooping-cough, 8 to scarlet fever, 3 to diphtheria, and 1 to "fever." In all, 96 deaths resulted from these principal zymotic diseases, against 102 and 119 in the two preceding weeks. These 96 deaths were equal to an annual rate of 3·2 per 1000, which was 1·7 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had increased from 32 to 41 in the three preceding weeks, declined again to 36 last week, and included 16 in Dundee, 14 in Glasgow, and 4 in Paisley. The deaths referred to whooping-cough, which had been 27 and 35 in the two preceding weeks, fell to 21 last week, of which 18 occurred in Glasgow. The fatal cases of scarlet fever, which had declined from 8 to 5 in the three preceding weeks, rose again to 8 last week, and included 2 in Glasgow, 2 in Edinburgh, and 2 in Dundee. The deaths from diseases of the respiratory organs in these towns, which had been 93 and 101 in the two preceding weeks, further rose to 106 last week, and exceeded by 37 the number in the corresponding period of last year. The causes of 30, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 22·8 and 21·8 per 1000 in the two preceding weeks, further declined to 20·3 during the week ending July 9th. During the thirteen weeks of last quarter the death-rate in the city averaged 23·5 per 1000, the rate during the same period being 16·4 in London and 19·7 in Edinburgh. The 136 deaths registered in Dublin during the week under notice showed a decline of 10 from the number in the preceding week, and included 6 which were referred to the principal zymotic diseases, against 8 and 11 in the two preceding weeks; of these, 3 resulted from whooping-cough, 2 from scarlet fever, 1 from "fever," and not one either from small-pox, measles, diphtheria, or diarrhœa. These 6 deaths were equal to an annual rate of 0·9 per 1000, the zymotic death-rate during the same period being 1·6 in London and 1·2 in Edinburgh. The fatal cases of whooping-cough, which had been 5 and 1 in the two preceding weeks, rose again to 3 last week. The 2 deaths referred to scarlet fever corresponded with the number recorded in the preceding week, while the mortality from "fever" showed a marked decline. The 136 deaths in Dublin last week included 27 of infants under one year of age and 31 of persons aged upwards of sixty years; the deaths of infants showed a slight decline from the number in the preceding week, while those of elderly persons showed an increase. Three inquest cases and 3 deaths from violence were registered; and 55, or more than a third, of the deaths occurred in public institutions. The causes of 9, or nearly 7 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING JUNE, 1898.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during June in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious diseases in the metropolis last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 7·1 per 1000 of the population, estimated at 4,504,766 persons in the middle of this year. In the three preceding months the rates had been 7·4, 7·1, and 7·2 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in Westminster, St. James Westminster, St. Giles, St. Martin-in-the-Fields, Strand, City of London, and St. Saviour Southwark; while they showed the largest excess in Fulham, Hackney, Holborn, Clerkenwell, St. Luke, St. George Southwark, St. Olave Southwark, and Bermondsey. Six cases of small-pox were notified in London during June, against 3, 4, and 1 in the three preceding months; of these, 2 occurred in London City, 2 in Lee, 1 in St. George Hanover-square, and 1 in Whitechapel. Only one small-pox patient was under treatment during the month in the Metropolitan Asylum Hospitals. The prevalence of scarlet fever in London during June showed a slight decline from that recorded in the two preceding months; among the various sanitary areas this disease showed the highest proportional prevalence in Fulham, Hackney, Clerkenwell, St. Luke, Mile End Old Town, St. George Southwark, and Woolwich. The Metropolitan Asylum Hospitals contained 2146 scarlet fever patients at the end of June, against 2358, 2270, and 2147 at the end of the three preceding months; the weekly admissions averaged 208, against 208, 218, and 223 in the three preceding months. The prevalence of diphtheria in London during June showed a slight further increase upon that recorded in recent months; this disease was proportionally most prevalent in Fulham, Chelsea, Hackney, Clerkenwell, St. Luke, Battersea, and Lewisham sanitary areas. There were 971 diphtheria patients under treatment in the Metropolitan Asylum Hospitals at the end of June, against 1009, 923, and 917 at the end of the three preceding

months; the weekly admissions averaged 134, against 129, 111, and 134 in the three preceding months. The prevalence of enteric fever in London showed an increase upon that recorded in the preceding month; among the various sanitary areas this disease showed the highest proportional prevalence in Islington, Stoke Newington, Hackney, Poplar, and Newington. The Metropolitan Asylum Hospitals contained 53 enteric fever patients at the end of June, against 64, 59, and 54 at the end of the three preceding months; the weekly admissions averaged 11, against 12 and 8 in the two preceding months. Erysipelas was proportionally most prevalent in Paddington, Marylebone, Bethnal Green, Newington, and Woolwich sanitary areas. The 21 cases of puerperal fever notified in London during June considerably exceeded the number recorded in the preceding month, and included 2 each in Marylebone, Islington, Hackney, St. George-in-the-East, Newington, and Wandsworth sanitary areas.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas of the metropolis, the deaths occurring in the institutions of London having been distributed among the various sanitary areas in which the patients had previously resided. During the five weeks ending Saturday, July 2nd, the deaths of 6321 persons belonging to London were registered, equal to an annual rate of 14·6 per 1000, against 20·8, 18·1, and 15·7 in the three preceding months. The lowest death-rates in the various sanitary areas were 9·5 in Hampstead, 10·9 in St. Martin-in-the-Fields, 11·5 in Lewisham, 11·9 in St. George Hanover-square, 12·0 in Stoke Newington, and 12·4 in Islington; the highest rates were 20·0 in St. George Southwark, 20·3 in Limehouse, 22·5 in St. Saviour Southwark, 24·0 in St. George-in-the-East, 24·6 in Strand, and 25·2 in Holborn. During the five weeks of June 801 deaths were referred to the principal zymotic diseases in London; of these, 283 resulted from measles, 57 from scarlet fever, 127 from diphtheria, 221 from whooping-cough, 24 from enteric fever, 89 from diarrhœa, and not one either from small-pox, typhus, or any ill-defined form of continued fever. These 801 deaths were equal to an annual rate of 1·9 per 1000; no fatal case of any of these diseases was registered during the month under notice either in Stoke Newington or in St. Martin-in-the-Fields; in the other sanitary areas they caused the lowest death-rates in St. George Hanover-square, Hampstead, St. Saviour Southwark, and Lee; and the highest rates in St. Luke, St. George-in-the-East, Limehouse, St. George Southwark, Rotherhithe, Woolwich, and Plumstead. The 283 fatal cases of measles were 56 below the corrected average number in the corresponding periods of the ten preceding years; this disease showed the highest proportional fatality in Marylebone, St. Luke, St. George-in-the-East, Rotherhithe, Wandsworth, Greenwich, and Plumstead sanitary areas. The 57 deaths from scarlet-fever were 31 below the corrected average number; the mortality from this disease showed no marked excess in any of the sanitary areas. The 127 fatal cases of diphtheria were 52 below the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Chelsea, Hackney, Clerkenwell, Bethnal Green, Limehouse, Poplar, and St. George Southwark. The 221 deaths referred to whooping-cough slightly exceeded the corrected average number; the mortality from this disease was highest in Westminster, Strand, Limehouse, St. George Southwark, Greenwich, and Woolwich sanitary areas. The 24 fatal cases of enteric fever were 21 below the corrected average number; the mortality from this disease last month showed no marked excess in any of the sanitary areas. The 89 deaths referred to diarrhœa were less than half the corrected average. In conclusion, it may be stated that the aggregate mortality last month from these principal zymotic diseases was nearly 21 per cent. below the average, the deaths from each of the diseases, except whooping-cough, being below the average.

Infant mortality in London, measured by the proportion of deaths of children under one year of age to registered births, was last month equal to 116 per 1000. Among the various sanitary areas the lowest rates of infant mortality were recorded in Chelsea, Hampstead, Hackney, St. Giles, St. Martin-in-the-Fields, Lewisham, and Lee; and the highest rates in Kensington, St. George Hanover-square, Strand, Holborn, St. George-in-the-East, St. Olave Southwark, and Woolwich.

THE SERVICES.

NAVAL MEDICAL SERVICE.

THE following appointments of Surgeons are announced:—William R. Trythall to the *Daphne;* G. McGregor to the *Mosquito;* R. S. Bernard to the *Vernon;* William H. Pope to the *Renard;* Henry W. Finlayson to the *Victory,* Archibald W. Campbell to the *Alarm;* George E. Macleod to the *Gossamer;* and Godfrey Taylor to the *Leda.*

ROYAL ARMY MEDICAL CORPS.

Captain J. C. Jameson has proceeded to the Royal Arsenal, Woolwich, for duty. Major E. M. Wilson has been selected for service in Egypt. Captain Cummins has been ordered to the Home District for duty. Lieutenant-Colonel B. W. Large has been placed under orders to embark for Egypt. The following officers have been appointed to medical charge of troops as stated: Major W. J. Naismith, A.M.R., 3rd Battalion Royal Scots Fusiliers, at Ayr; Captain W. B. Macdonald, A.M.R., South-East of Scotland Artillery, at Dunbar. The annual gymkhana of the detachment at Gibraltar was held at North Front on June 20th and was a complete success. Lieutenant-Colonel Gunning and many well-known officers were present, whilst the general attendance greatly exceeded that of any previous gathering. Captain J. Thomson has embarked for service in Egypt. Two detachments have recently started from Aldershot for the Soudan. The first left on July 1st and consisted of Major Dodd, in command, Captain Clarkson, Lieutenant Lowsley, and 119 non-commissioned officers and men. The second left on July 13th and consisted of 133 non-commissioned officers and men, under Lieutenant-Colonel Clery, with Lieutenant-Colonel Carey and Lieutenant and Quartermaster Goater. Major W. G. Birrell and Major F. W. C. Jones and Lieutenant E. Brodribb have embarked for service in Egypt. Lieutenant-Colonel G. A. Hughes handed over the medical charge of the Station Hospital, Canterbury, to Major H. J. Barratt on July 1st.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of Surgeon-Captain Bourke have been placed at the disposal of the Government of Bombay as Officiating Chemical Analyser. The services of Surgeon-Captain Heard are replaced at the disposal of the Military Department. The services of Surgeon-Captain Burnett are placed at the disposal of the Government of Bombay. The services of Surgeon-Captain Buchanan are placed at the disposal of the Government of Bengal for gaol duty. Surgeon-Lieutenant-Colonel Cook and Surgeon-Captain Donovan are appointed to act as Surgeons, fourth district, Madras. Surgeon-Captain Mitter is appointed to act as District Medical and Sanitary Officer, Ganjam, and Superintendent of Gaol, Berhampore, during the employment of Surgeon-Captain Pereira on other duty. Surgeon-Lieutenant-Colonel Duncan (Army) is appointed to the Civil Medical Charge of the Almora District in addition to his military duties. Surgeon-Captain Vost, Civil Surgeon, Gonda, is appointed to hold Visiting Medical Charge of the Bahraich District in addition to his other duties. Surgeon-Major O'Sullivan (Army) is appointed to the Civil Medical Charge of Roorkee in addition to his military duties. Surgeon-Major MacLaren, Civil Sugeon, Benares, is appointed to hold Visiting Medical Charge of the Jaunpur District in addition to his other duties. The services of Surgeon-Captain Deare and Surgeon-Captain Oldham are replaced at the disposal of the Government of Bengal. The services of Surgeon-Captain Gwyther are placed at the disposal of the Government of Bengal for employment on plague duty. The services of Surgeon-Lieutenant Clemesha are placed at the disposal of the Government of the Punjab for employment on plague duty. The services of Surgeon-Captain Dewes and Surgeon-Captain Prasad are replaced at the disposal of the Government of Burmah. The services of Surgeon-Captain Dallas are replaced at the disposal of the Chief Commissioner of the Central Provinces. Surgeon-Major Shore (Bengal) is appointed to be Residency Surgeon in Newar. Surgeon-Major Woolbert is appointed to officiate as Medical Officer, Kotah and Jhalraptan. Brigade-Surgeon-Lieutenant-Colonel Hall (Bengal) is granted the temporary rank of Surgeon-Colonel whilst officiating as Inspector-General of Civil Hospitals, North-Western Provinces and Oudh, vice Surgeon-Colonel Warburton, on leave. Surgeon-Captain Jordan is appointed to act as Deputy Sanitary

Digitized by Google

Commissioner, Metropolitan and Eastern Bengal Circle, and to be an Assistant Health Officer of the Port of Calcutta in addition to his own duties. Surgeon-Captain Vaughan is reappointed to be Deputy Sanitary Commissioner, Western Bengal Circle, and is also placed on special duty in connexion with anti-cholera inoculation. Surgeon-Captain Calvert is appointed to act as Civil Surgeon of Darbhanga during the absence on deputation of Surgeon-Captain Green. Surgeon-Captain Birdwood, Officiating Civil Surgeon, Ghazipur, is appointed to hold Visiting Medical Charge of the Ballia District in addition to his other duties. Surgeon-Lieutenant Stevenson is transferred from plague duty at Hardwar to platform inspection duty, Saharanpur. Surgeon-Lieutenant-Colonel Maitland has been appointed Senior Physician of the Madras General Hospital. Numerous cases of enteric fever, supposed to have been contracted on the march up from the plains, have occurred among the troops at Dalhousie.

MILITIA MEDICAL STAFF CORPS.

The Hants Companies of the Militia Medical Staff Corps arrived at the Royal Victoria Hospital, Netley, on July 4th for their annual training. They are to remain at Netley twenty-seven days and are under the command of Captain W. M. O'Connor, M.D. Dub.; Captain H. E. Mortes is also on duty with his company. The strength consists of 46 privates and 11 non-commissioned officers. The companies are on duty daily at the Royal Victoria Hospital and parades are held daily for company and stretcher drill.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant-Colonel A. T. Norton, C.B., having resigned his appointment in the Volunteer Medical Staff Corps and Surgeon-Captain R. Bevan, having resigned his Volunteer appointment, cease to belong to the Army Medical Reserve of Officers.

VOLUNTEER MEDICAL STAFF CORPS.

The London Companies: Ernest Blechynden Waggett, M.B. Cantab., appointed to be Surgeon-Lieutenant.

THE SPANISH-AMERICAN WAR.

The events which have taken place since our report of last week, in which the complete destruction of Admiral Cervera's fleet and the unsuccessful attack of General Shafter's force on Santiago were referred to, have been followed by some detailed information concerning these occurrences. The information is still very incomplete, however, but the fact remains that there is an end to the naval power of Spain as far as this war is concerned. Admiral Camara's fleet remains, no doubt, but Spain has seemingly very little to hope for in that direction. It is now on its way back to Spain from Suez for the protection of Spanish seaports, but the United States are despatching Commodore Watson's squadron to meet it. Nothing has been more surprising than the collapse of the Spanish navy and the tactical mistakes and apparent incapacity of all concerned in regard to it. General Shafter has been strongly reinforced, and with the artillery and the number of men now at his command, Santiago, which is closely invested, is bound to be taken unless surrendered. The troops composing General Shafter's force showed great dash and bravery in their late engagement before Santiago, but the expedition was altogether premature and from a military point of view a mistake. Without a strong force of artillery the task of driving the Spanish troops out of their entrenchments could not be successfully undertaken. The total loss to the attacking force was heavy: it amounted to 1593, of whom 300 were killed, including 22 officers. No returns have been published of the Spanish losses on that occasion. There does not seem to be much sickness so far among the American troops in Cuba, but they have undergone much exposure and hardship in addition to their losses in fighting. There were about 150 cases of fever in hospital. As is almost invariably found to be the case in such expeditions as that which the United States troops have undertaken in Cuba, the great difficulty is one of transport. From the published reports it would appear that owing to this cause the field hospital and commissariat arrangements have been attended with extreme difficulties and have exhibited many shortcomings. The unpreparedness on the part of both belligerents is one of the remarkable features of the war. Spain was, it is true, exhausted when she began it by the enormous losses she had already sustained in her ineffectual attempts to stamp out the insurrection in Cuba. Still, she had a large army in occupation of that island and a fleet which, if not of equal strength to that of her adversary, was capable, with skilful management, of doing a great amount of damage and mischief in various ways. Nothing, however, is to be learned from the action of her fleet for it is not likely that any other nation would adopt and follow her futile tactics. The Americans, on the other hand, have been audacious and enterprising and surprisingly successful at sea, but far less so on shore, and the Spaniards, if they are still determined upon fighting it out, may give the United States Government an infinity of trouble, although the end is absolutely certain to be in favour of the latter. It seems highly probable that Spain will soon be compelled to come to terms with her adversary.

THE SICK AND WOUNDED IN EGYPT.

Major-General Frank S. Russell's communication to the *Times* of July 11th on the above subject deals in a judicious and temperate spirit with the real and alleged shortcomings at the battle of Atbara and with the provision which should be made to meet the medical and transport requirements of the Anglo-Egyptian force in the forthcoming expedition to Khartoum. We have reason to hope that whatever is practicable in these respects will be done—as should certainly be the case—when the advance during next month takes place. Efficiency and not economy merely is the first aim in war.

INDIAN FRONTIER CAMPAIGN.

A gratuity will be granted to all officers and men employed in the recent operations on the North-Western Frontier. It will be at the rate of 24 rupees per share for the British and 12 rupees for native soldiers. A general will receive 400 shares; a colonel on the staff and a surgeon-colonel, 40 shares; a colonel, lieutenant-colonel, brigade-surgeon-lieutenant-colonel, and surgeon-lieutenant-colonel, 32 shares; a major and a surgeon-major, 16 shares; a captain and a surgeon-captain, 12 shares.

MEDICAL CHARGE ALLOWANCE.

We learn from the *Pioneer Mail* of June 24th last that it has been decided that Indian medical officers shall in future receive an allowance of Rs. 100 a month for the medical charge of each section of a field hospital in lieu of consolidated salaries for medical charge of such hospital as a whole, but the allowances to Army medical officers for the charge of field hospitals and to officers of both services for charge of general hospitals shall remain unchanged.

LEAN'S ROYAL NAVY LIST.

The July number of this valuable work of reference has now appeared and requires no recommendation to those who are aware of the extensive and varied information which it uniformly contains. The publishers are Messrs. Witherby and Co., 326, High Holborn, and 4, Newman's-court, Cornhill.

ARMY MEDICAL SCHOOL, NETLEY.

The seventy-sixth or Summer Session of the Army Medical School, Netley, will be brought to a close on July 29th, when the prizes will be distributed and an address delivered by Lord Lister. The Netley examination will commence on July 21st and will terminate on July 27th.

Dr. Samuel O. L. Potter, M.D. Jefferson Med. Coll., Philadelphia, M.R.C.P. Lond., of San Francisco, has been commissioned as a Brigade-Surgeon of Volunteers with the rank of Major in the United States Army and assigned to the expeditionary forces to the Philippine Islands.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund, held on July 12th, Inspector-General W. H. Lloyd being in the chair, the sum of £66 was distributed among the several applicants.

PROPOSED APPOINTMENT OF A MEDICAL OFFICER OF HEALTH.—At the meeting of the Somerset County Council held on June 28th the committee appointed to consider the question recommended that the Council should appoint a county medical officer of health who should devote his whole time to the duties at a salary of £500 per annum exclusive of travelling allowances. The consideration of the subject was deferred to the October meeting.

Correspondence.

"Audi alteram partem."

"VITALITY."

To the Editors of THE LANCET.

SIRS,—I have read Dr. Lionel Beale's "Appeal and Challenge" in an entirely unprejudiced spirit, but the former does not convince my understanding and I am therefore reluctantly compelled to take up the gauntlet he has thrown down to his brother practitioners.

It seems to me more logical and more easy of comprehension to regard *vitality* as a peculiar play of forces belonging to the inanimate world than as a force *per se* essentially different in nature from these forces. On the former assumption vitality is due to the working of forces inherent in the elements of bioplasm and of those environmental forces which share in the reaction between the bioplasm and its environment. If vitality is distinct from these forces it must exist apart from matter and if such is the case how and where, I would ask, does it exist? Dr. Beale would seem to argue that it is a sort of intelligence existing apart from matter, capable of directing the operation of the forces belonging to matter—a position as untenable as that of the spiritualists, who assume that the immaterial can act upon the material.

Dr. Beale will, I presume, allow that the quantity of vitality in an organism tends to vary with its bulk. Other things equal, the quantity of vitality in an organism containing a million cells is a million times greater than that of a one-celled organism. The human organism starts practically as a single cell, but by the process of segmentation it develops into one consisting of millions of cells, and when this has happened the sum of its vitality is many million times greater than that of the primitive embryo. Now whence has come this augmentation of vitality? Force, like matter, cannot be created any more than it can be annihilated. The answer surely is that it comes in the last resort from the nutrient fluids, oxygen, &c., conveyed from the world without. It is carried into the house by the milkman, grocer, butcher, and is borne in by the atmosphere.

I cannot think of vitality as a force *per se*. I conceive that the behaviour of bioplasm is essentially the outcome of physical conditions—that it depends upon the nature and arrangement of the atoms in the bioplasmic molecules, upon the arrangement of the molecules among themselves—upon the structure of the bioplasm in fact—and other purely physical conditions. Dr. Beale's assumption that bioplasm is structureless is to my mind wholly illogical. He assumes it to be so because he is unable to detect any structure in it. In our journey into the world of the infinitesimal we come sooner or later to a point at which we cease to detect structure, but this point is a purely arbitrary one and is continually receding as our means of investigation improve. It marks the limit of our perceptions aided by the most powerful microscopes we can devise, but bears no relation whatever to any grand fact of nature. To my mind bioplasm is highly complex in structure as compared with inorganic matter. We are so apt to forget that the world of the infinitesimal is as unlimited as that of the immense. If we take a single cell as our unit of size, then as regards its relation to space it is no nearer the limit of the infinitely small than of the infinitely great, for neither has any limit; our cell may be divided or multiplied *ad infinitum*. Imbued with this conception we shall the better realise the vastness of the infinitesimal, so to speak, and shall be cautious in regarding bioplasm as altogether devoid of structure.

One further point. On Dr. Beale's view it is most difficult to account for the evolution of life on this planet. If vitality is not correlated with the forces of inanimate nature whence came it? On the assumption that it is a peculiar play or coördination of physical forces, the evolution of life, the coming-into-being of vitality, is to be explained by the coming together of certain atoms in a peculiar way. For my part I believe in the spontaneous evolution of life. The fact that those forms of life which we regard as the most primitive cannot evolve from inanimate matter is no argument against this belief. A proper appreciation of the vastness of the infinitesimal prepares us for the conclusion that the most primitive forms of life known to us are highly complex as compared with those which are actually the most primitive. Such I should expect to consist of a comparatively few molecules and to be altogether too minute for detection by the most powerful microscope.

I am, Sirs, yours faithfully,

Wimpole-street, W., June 26th, 1898. HARRY CAMPBELL.

PENALTIES FOR UNREGISTERED PRACTICE.

To the Editors of THE LANCET.

SIRS,—In view of the general interest, public as well as professional, aroused by the Collins case, the time seems favourable, in spite of the lateness of the session, for an attempt to penalise disregistered practitioners, to the extent of disqualifying them from further practice. As the case stands Dr. Collins retains his degree, in spite of a double conviction for felony and a sentence of penal servitude, and signs are not wanting that other cases of the same kind may speedily transpire. In view of these facts the council of the Incorporated Association of Medical Practitioners has determined to seek an interview with the Home Secretary at once, with the view of inducing him to bring in a Bill on the lines of the one which I enclose.

We recognise fully that the time available is very short, but there can be little doubt that if the profession will bestir itself the object may be effected. Every day is, however, of consequence, and we earnestly appeal to every practitioner who has the dignity of the profession and the safety of the public at heart to communicate with his Parliamentary representative at once to secure his support for the proposal. There is no doubt that the action of the Home Secretary will be greatly influenced by the prospects of the measure as regards opposition, and time is of the last importance. I shall be most happy to supply a copy of the proposed measure to any member of the profession who may apply to me for one enclosing a halfpenny stamp, and shall be glad to hear from any who would be willing to join with me in impressing its importance upon our legislators.

I am, Sirs, yours faithfully,

EDWD. C. BOUSFIELD.

363, Old Kent-road, S.E., July 11th, 1898.

[ENCLOSURE.]

AN ACT to prevent persons who have been removed from the Medical Register under the provisions of Section XXIX. of the Medical Act, 1858, from continuing to act as Medical Practitioners.

WHEREAS it is expedient that persons who have been removed from the Medical Register by the General Council of Medical Education and Registration under the powers conferred upon it by the twenty-ninth Section of the Medical Act, 1858, should be prevented from continuing to act or practise as Medical Practitioners: Be it therefore enacted by the Queen's Most Excellent Majesty, by and with the Advice and Consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the Authority of the same, as follows:—

1. This Act may for all purposes be cited as "The General Medical Council (additional Powers) Act."

2. This Act shall commence and take effect from the First Day of September, One thousand eight hundred and ninety-eight.

3. Any person whose Name shall have been removed from the Medical Register by the General Council of Medical Education and Registration, under the powers conferred upon the said Council by the twenty-ninth Section of the Medical Act, and who shall thereafter practise Medicine or Surgery, or Medicine and Surgery, as the case may be, in any part of the United Kingdom of Great Britian and Ireland, shall, upon a summary Conviction for any such Offence, pay to the said Council a Sum not exceeding Twenty Pounds.

4. The General Council of Medical Education and Registration shall be entitled to receive all Fines inflicted upon Offenders convicted under Section XL. of the Medical Act.

MYDRIN: A NEW MYDRIATIC.

To the Editors of THE LANCET.

SIRS,—THE LANCET of July 2nd contains an interesting note by Dr. Sydney Stephenson on a New Mydriatic. He kindly alludes to my observations on this mydriatic in the *Clinical Journal* in 1895, which were, I think, the first published in this country. I would like to add that I again refer to the value of mydrin in my volume on the "Examination of the Eye" (Pentland), published this year. My object in writing now is to reiterate my opinion of the efficacy of mydrin as a rapid pupil dilator without affecting the accommodation and the effects of which quickly pass off, features marking it as specially adapted for producing mydriasis for ophthalmoscopic purposes. The present price of the drug is, however, almost prohibitive of its use. I

Digitized by Google

understand that it still costs something like 25*s.* a drachm, but of course a demand for it would soon bring about a reduction in price. It is further to be desired that some firm should furnish the drug in the form of gelatin discs of such excellence, for instance, as Wyeth's discs of homatropine.

I am, Sirs, yours faithfully,

July 13th, 1898. SIMEON SNELL.

COPYRIGHT IN PRESCRIPTIONS.

To the Editors of THE LANCET.

SIRS,—Now that the Royal Commission on Copyright is sitting would it not be a good plan to devise a scheme for bringing prescriptions under the law of copyright? I mean that it should become legal for medical men to retain the copyright in their prescriptions after a certain limited time after their issue. It is very common for patients to have some prescription which suits them renewed perhaps hundreds of times even to the end of their lives, so that the authors of the prescriptions get compensated with absurd insufficiency by the single fee they receive. The injustice of the present state of things is so palpable and our loss so enormous thereby that there can be no object in disguising the sordid nature of the proposal. It is quite possible that the injury done to us might be obviated in some such way as I suggest.—I am, Sirs, yours faithfully,

F. LUCAS BENHAM, M.D., M.R.C.P. Lond.

Elizabeth-street, S.W., July 12th, 1898.

HOSPITAL REFORM.

To the Editors of THE LANCET.

SIRS,—In the paper I read recently at the United Service Institution embodying certain suggestions as to the reform of the casualty and out-patient departments of London hospitals I made a statement which I have since discovered is not warranted by fact: it was to the effect that in Scotland and in Ireland drugs were not given in the medical out-patient departments of the hospitals. Before I left the Institution I was informed that I was mistaken with regard to Ireland and Mr. Garrett Horder writes to me under date July 6th as follows: "I have been making inquiries of the system adopted in the principal Scotch hospitals and I find that as a rule medicines are supplied to the out-patients."

I regret having made the assertion, but I regret still more that the fact is not as I supposed, as I believe the plan to be a good one.—I am, Sirs, yours faithfully,

W. HENRY KESTEVEN.

Hendon, N.W., July 8th, 1898.

"BLOOD-PRESSURE IN THE INSANE."

To the Editors of THE LANCET.

SIRS,—The article on the above subject from the pen of Dr. Maurice Craig, which appears in THE LANCET of June 25th, is of such importance that I venture to offer some observations which are based upon five months' constant use of Barnard and Hill's sphygmometer, which has been brought into requisition to such good purpose by Dr. Craig, with reference to those who are relatively sound in mind. Dr. Craig is careful to point out that although high intra-arterial pressure is uniformly found to exist in cases marked by depression, especially in melancholia, and infra-normal blood-pressure in those who exhibit excitement and mania, he does not for one moment believe that "any amount of altered blood-pressure can *per se* produce insanity in a perfectly stable person," and suggests that "similar conditions of blood-pressure may exist in other individuals without inducing, or being associated with, mental alienation." In that view he is perfectly correct. Indeed, as far as my experience goes, not only is such the case, but in many persons a pressure of 200 and more mm. Hg. may exist without any psychic effect other than such depression of spirits and gloominess of anticipation as are constantly met with in people who pass as being in average health or as being affected with nothing more grave than the mental state commonly associated with gouty conditions.

Writing on the subject of chronic diseases of the heart in 1895[1] I stated that "intolerance of sound, irritability, difficulty of mental concentration, lessened power of work, depression amounting in some cases to despondency, and night alarm are of common occurrence," and that with rehabilitation of the heart and vessels "all such nerve suffering vanishes like a dream and the spirits rise to a plane of hope and energy." With the aid of the sphygmometer I have been able to verify the fact that depression, the indefinable sense of impending disaster, irritability, and insomnia are generally associated with high blood-pressure and have observed that the lowering of that pressure is followed by very satisfactory results. The instrument referred to indicates the line of treatment which may be required. Of cases of mental excitement associated with infra-normal pressure I have seen so little that I do not venture to express an opinion. There is, however, one point in Dr. Craig's article which, if I may venture so to say, requires further and closer examination, and that is the state of the bowels. He attaches much importance, and doubtless in the main rightly, to the relief of constipation and to the maintenance of somewhat free action of the bowels; but it must not be overlooked that a considerable proportion of the subjects of mental depression with high blood-pressure suffer from chronic intestinal catarrh, involving from two to three actions of the bowels a day, of which only the first may be formed or fragmentary and the others fluid. With regard to the relation of the state of the bowels to the condition under consideration, it is suggested that the depression may be due to sensory nerve stimulation affecting the general arterial pressure through the splanchnic mechanism rather than to self-infection. If such be the case the existence of fæcal accumulation and of inordinate action of the bowels must both be regarded as having a similar disturbing effect on the sensory nerves in question, and I do not deny that such may be the case. On the other hand, I do think that the question of auto-toxication cannot be excluded, the more so as, whether the condition relieved be fæcal accumulation or chronic intestinal irritation, an important point is gained in the lowering of blood-pressure and at the same time a striking change is exhibited in the renal function by the great increase of the excretion of urine and the diminution of its toxicity. The question, therefore, arises: What may be the clinical and therapeutic import of the association between mental depression and high blood-pressure? The observations of some years, which have been strongly confirmed since I have brought the sphygmometer into general use, show that those conditions of the blood which are betrayed by scantiness or concentration of the urine and by increased toxicity are themselves the causes of contraction of arterioles, of high intra-arterial pressure with increase of peripheral resistance, of venous engorgement, and of deficient oxygenation of the blood, and that all these conditions, which together constitute a serious pathological condition, are rapidly relieved by increase of arterial capacity and the relief of peripheral resistance resulting in improved oxidation and metabolism and the repair, among others, of the cerebral and other nerve tissues. It is a matter of observation that fæcal impaction and chronic looseness may both be associated with high intra-arterial pressure; and there are strong clinical grounds for believing that the presence of imperfectly digested substances in the descending colon is causatively connected with re-sorption of toxins which should be excreted and with blood-contamination with products of fermentive decomposition. For these reasons I think that auto-toxication is an important factor in the production of mental depression.

In illustration I give, from many others, the following cases. On May 26th I saw a woman, aged thirty-seven years. Her radial pulse was thready and the pressure was 160 mm. Hg. The apex was 1 in. outside the nipple line. There was dyspnœa on the levels and inclines. She woke with a sense of impending suffocation associated with pain in the præcordium and the inner aspect of the left upper arm. The bowels acted twice or thrice daily; the motions were yellow, the second and third being liquid. The patient was very depressed and unwilling to submit to treatment, as she said that she could never be better; she was never without headache, extending from the frontal region to the vertex and occiput. On June 1st the pressure was 126 mm. Hg., she had scarcely any headache, she felt and looked better, and was more hopeful. On the 7th there was no headache, the appetite and spirits were good, the apex was in the nipple line, the bowels acted once daily, and the motions were healthy. When last seen, on June 30th, she was very bright and cheerful; she had no headache and slept well; the bowels were regular; there

[1] The Schott Treatment of Chronic Diseases of the Heart.

Digitized by Google

was no recurrence of anginous pain, and the pressure was from 122 to 124. The second patient was seen on May 14th. She was a woman aged thirty-one years. Pressure was 156 mm. Hg.; exertion brought on præcordial pain extending to the inner aspect of the left forearm; the apex was a quarter of an inch outside the nipple line; the second sound at the base was accentuated in both areas; the bowels acted once daily, the motions being always liquid and brown; she had general rheumatic pains and refused to eat and to speak; she cried frequently and was generally very depressed. She had headache at the vertex on waking every morning. On June 28th the pressure was 122; the patient was very cheerful and in good health; there was no anginous pain; the apex was half an inch within the nipple line; the heart sounds were normal; the motions were healthily formed; and there was no headache.

In both these cases remedies were given to retard the action of the bowels and to promote intestinal antisepsis, in conjunction with small doses of iodide of potassium and 3 gr. daily of nitrite of sodium. The first patient, in addition, had some artificially prepared Nauheim baths. I may add that prior to reading Dr. Craig's article I had suffered for two months from headache at the vertex, coming on daily at about 6 A.M. and subsiding after my morning bath. On taking my pressure at bedtime I found it to be 170 mm. Hg. I took 2 gr. of nitrite of sodium and woke the following morning with a clear head. After breakfast the pressure was 122 mm. Hg. The two following nights I took no nitrite with the result that I had headache in the mornings. Since then I have taken 1 gr. each night with good results. At the present moment (midnight), 24 hours since taking the last dose, the pulse pressure is 130 mm. Hg.

I am, Sirs, yours faithfully,

Upper Brook-street, W., July 4th, 1898. W. BEZLY THORNE.

"THE ALLEGED DEARTH OF QUALIFIED ASSISTANTS."

To the Editors of THE LANCET.

SIRS,—If "Practitioner's" ex-employer was making only £700 a year and yet had more work "than one man could possibly do," one cannot help thinking that his fees must have been a good deal below the ordinary standard. And I cannot understand how a man should have to work "practically night and day" to earn £400 a year unless under similar circumstances. My own income is just about that figure, but though I walk my rounds and do everything myself I cannot complain of want of leisure. When men find that it is impossible to get an assistant unless they pay him sufficient to give him a moderately respectable return upon his invested capital of money, brains, and hard work, they will begin to find, too, that branch practices, sixpenny fees, and penny clubs are as unremunerative as they are selfish and undignified. The result will be that everybody will have the chance of making a modest but sufficient income. The recent action of the General Medical Council seems (if the jeremiads which some of your correspondents are pouring into our ears be not exaggerated) likely to bring about this result. It is a consummation devoutly to be wished.

I am, Sirs, yours faithfully,

July 10th, 1898. PRACTITIONER TOO.

To the Editors of THE LANCET.

SIRS,—"Practitioner" gives another, but hardly the reverse, side of the picture. No one questions that there are thousands of practitioners for whom a young man may act as assistant with the greatest satisfaction and mental profit. But that is hardly the point in question. The practical point is the obvious injustice of a man, such as "Practitioner" himself, spending some seven or eight years in study and probably about £1000 to learn his profession, and then only receiving a small pittance which can leave him no margin to save. If he serves with a definite understanding that he will receive a share of the practice in time the matter is not altogether objectionable, but a very large majority of assistants have no such understanding, but give their services simply for cash and because they have not the wherewithal to buy themselves a practice. The public squeezes the principal and the principal the assistant, and so things will go on until the profession is so flat that it can be squeezed no more, and then perhaps it will begin to resist the pressure. One would like to know how much the parish and the clubs were paying "Practitioner's" hard-used principal. I have little doubt that it was Poor-law work done at a loss and club work at some ridiculous price which compelled the unfortunate man to so squeeze his assistant. If there is now a dearth of qualified assistants the principals will have to bear the pressure themselves and I hope they will soon begin to resist. It is only the threat of advertising for another medical man which keeps many of the Poor-law medical officers from demanding a reasonable wage, and if they could be assured that there was no longer a cloud of aspirants hovering over them ready to pounce on the smallest appointment they would begin to resist the ever-increasing pressure. The effect would soon be felt all round and "Practitioner's" description of the profession as a life of hardship, a scanty income, constant harass, and too often but little gratitude, accurate enough now, would soon cease to be true.

I am curious to learn what fee, if any, will be paid the medical officers who are to call on the unvaccinated infants with offers of gratuitous glycerinated lymph. This would seem a good opportunity for them to ask a reasonable fee and one which would at least cover their travelling expenses. Probably they will be asked to do it for nothing on the ground that it will be a splendid advertisement. "Practitioner" has my hearty sympathy if he has to do the work of two men to earn a net income of £200 a year, but let me urge him not to attempt to lessen the pressure by placing part of it on a younger man, but rather take the manlier course of demanding a fair wage from those who use his services. I know it is folly for a man to quarrel with his bread-and-butter, but it is passing strange that the coal-miner will leave his work and starve rather than take a penny less than what he believes is his due, while the hard-worked practitioner dare hardly hint at the request for a slight increase in his starvation wages. With apologies for such a lengthy letter,

I am, Sirs, yours faithfully,

July 9th, 1898. ANOTHER G.P.

To the Editors of THE LANCET.

SIRS,—I think there is little doubt that the average income of medical men, especially those living in country parts, does not exceed £400 a year. The contrast between this amount earned in large towns and in the country is very considerable, as in the former case this income can be obtained on foot or with occasional hiring, whereas in the country it means the necessity of keeping two horses, which, with their necessary expenses of groom, &c., reduces the income by quite a third. In addition to this, in many of the country parts lack of educational facilities necessitates a man with a family sending his children to boarding schools instead of day schools, by which the expense is greatly increased. I speak from experience and say were I not fortunate enough to have some private means I am unable to see how I could have educated my family, as it is with great difficulty I have given them a fair general education at a cost of about £1500, but cannot afford to bring them up to a profession, consequently my two sons have gone abroad. At the commencement of my career I was an assistant for several years at £60 a year in-door and was treated as a gentleman except in one instance. My opinion is that from £60 to £80 a year in-doors ought to be fair remuneration for an assistant, as it does not differ much from what the average practitioner really gets, as board and lodging with proper treatment ought to represent £100 per annum. I think a fair estimate of a country practitioner's expenses would be: horses, grooms, and drugs, £180; rent, rates, and taxes, £60; leaving £160 for household and other expenses.

I am, Sirs, yours faithfully,

July 11th, 1898. MEDICUS.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Plague in Bombay, Calcutta, and Karachi.—Degrees of Virulence during an Epidemic.—Medical Men and Nurses on Plague Duty.

IN Bombay the general health of the population has greatly improved. A few cases of plague still continue to be reported, which must remind the authorities that this

Digitized by Google

disease has not yet been exterminated from the city. An increased number of cases of relapsing fever have occurred, but the mortality from this disease is small. In Calcutta the plague seems to be very gradually increasing. It will be remembered that a very gradual development characterised the first outbreak in Bombay. The totals now stand at 104 cases and 77 deaths—a mortality of 74 per cent. Inoculation with Haffkine's prophylactic fluid is becoming more popular, the total number inoculated up to June 9th being 1239. Large numbers of the people continue to leave the city and judging by the favourable results of clearing out large sections of a population and putting them in health-camps the greatest safety after all probably lies in flight. It is interesting to note the rise in virulence of the plague as an epidemic advances. In Karachi the present outbreak commenced at the end of March. For the first week in April the mortality of plague cases was 55·5 per cent., for the second week 63·3 per cent., for the third week 74·6 per cent., for the fourth week 66·7 per cent., for the fifth week 77·9 per cent., for the sixth week 79·8 per cent., and for the seventh week 89·8 per cent. This fearful mortality occurred just after the highest plague figures had been recorded. From this time, however, the epidemic rapidly declined. For the eighth week the mortality of plague cases sinks to 77·5 per cent., which it also maintains for the ninth week, and for the tenth week it sinks to 73·7 per cent. The epidemic has been shorter in duration but more severe in character than the outbreak last year. The numbers show that compared with the population it has been twice as deadly as even the second outbreak in Bombay. The later season and the exodus of people probably account for its shorter duration. The mortality of this outbreak has been 87·4 per cent.; last year it was 81 per cent.

Considering the various dangers which the English medical men and nurses engaged in attendance on plague cases have incurred not only from plague and other diseases but in very many instances from physical injury, it would be justly a reward of merit if the Government of India were to recognise their services by some mark of distinction. The duties of both medical men and nurses have been arduous and for the most part uninteresting: the climate is trying for new-comers and the pay is not only considerably lower than their position warrants but is inadequate to the services rendered. Should plague develop as the colder weather advances, and should the Government of India require further assistance, I strongly advise both medical men and nurses not to come to India at the present rates of pay. Expenses are heavy, it is only a temporary appointment, there is no prospect after the plague is over, inconveniences are numerous, and you are perhaps isolated from all your friends.

June 16th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Mayor of Bootle.

DR. JOHN MCMURRAY, the popular mayor of Bootle, will be formally presented at an early date with his portrait reproduced in oils. A short time ago a number of representative gentlemen in Liverpool organised a subscription for the purpose. The painting has been executed by Mr. C. J. Orchardson and is to be exhibited in the Walker Art Gallery at the forthcoming Liverpool autumn exhibition.

Health of Birkenhead: Dr. Marsden's Report for 1897.

The annual report of the medical officer of health of Birkenhead on the sanitary condition of the borough just issued records a steady improvement in the health of the inhabitants, the death-rate being lower than in any year since 1881 with the single exception of 1894. The density of the population is now 28·83 per acre over the whole borough, against 20·06 at the time of the incorporation twenty years ago, the population being then 77,260 compared with 111,000 in the middle of 1897. The pressure is chiefly felt in the townships of Birkenhead and Tranmere; the density in Birkenhead being 50·62 per acre, against 39·33 in 1878, and in Tranmere 31·83 per acre, compared with 17·64 in the same year. During the year 1897, 4982 nuisances were reported, 4666 being abated without compulsion. Dr. Marsden remarks that in some hotels girls follow their occupation for upwards of 100 hours a week, and he considers it desirable that the benefits of the Shop Hours' Act should be extended to them also, restricting their working hours to 74 per week. The medical officer states that the quality of the water is excellent and that the average supply is 17 gallons per head. As far as bacteriological examination of the water is concerned it was found that the Spring Hill well is the most perfect, the Borough-road coming next in order. Dr. Marsden has not confidence in the future quality of the Flaybrick-hill source. Altogether the report as affecting the water-supply is very satisfactory. During the past year 402,652 lb. of meat were condemned as unfit for human food, representing 124,662 lb. more than were seized in the previous year. The total number of seizures of unwholesome food was 1618. Of the total quantity of meat seized 377,869 lb. were condemned at the Woodside and Wallasey lairages. During the year numerous complaints had been received of offensive effluvia from open sewer ventilators. The medical officer expresses the opinion that the ventilators are a nuisance and in narrow streets a distinct danger and suggests that the whole of the grids should be closed and all interceptors between house drains and the sewers removed. Every ventilating shaft attached to the house drains would then act as a ventilator for relieving the gaseous pressure in the sewers, while affording absolute immunity from the danger of forcing the house-traps. During the year 2028 cases of infectious diseases were notified, being 1050 less than in 1896. The birth-rate was 31·68 per 1000 of the population for the whole borough and the death-rate was 18·39 per 1000 of the population. The birth-rate was 0·8 per 1000 lower than the average for the preceding ten years, and the death-rate was 1·5 per 1000 lower.

Children's Convalescent Home, West Kirby.

The Lord Mayor of Liverpool and the Lady Mayoress visited the West Kirby Convalescent Home on June 29th and expressed themselves highly pleased with all the arrangements provided for the comfort of the children. Last year 832 children received the benefits of the institution, staying an average time of three and a half weeks. The average number of children in the home during the year was 57. There are 76 children in residence at the present time, and so great is the demand for admission that all the prospective vacancies are filled up to the end of July. The committee contemplate the extension of the building by the erection of a new wing at a cost of £3500, which will be begun as soon as the sum of £2000 shall have been guaranteed. Subscriptions amounting to £900 have already been received towards this purpose.

Bequests to Liverpool Hospitals.

By the will of the late Mr. Andrew Gibson, shipowner, of Liverpool and West Kirby, the following charities have received £100 each: the Liverpool Royal Infirmary, the Royal Southern Hospital, and the Liverpool Northern Hospital.

New Cheshire Infirmary.

Mr. W. H. Verdin, D.L., is about to present to the towns of Winsford and Middlewich a new infirmary, which by special permission of Her Majesty is to be called the Albert Infirmary. Mr. Verdin will also provide for the furnishing of the infirmary with a complete equipment. The Duke of Westminster has consented to perform the opening ceremony.

July 12th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Meeting of the British Medical Association at Edinburgh.

THE recent Army Warrant dealing with the reconstruction of the Army Medical Service has given rise to the hope in some quarters that a corresponding alteration will ere long be made in the Volunteer Medical Service. With a view to discussing the position it is hoped that a meeting of Volunteer medical officers may be held in Edinburgh during the visit of the Association. Information regarding this meeting may be obtained in the reception room.

Hawkhead Asylum.

The hospital in connexion with this asylum was formally opened on July 8th. A large company of ladies and gentlemen, including the representatives of the Govan Parish

Digitized by Google

Council, Dr. Clouston, Dr. Yellowlees, and others, travelled by special train from Glasgow to attend the ceremony. It is now seven years since building operations were commenced and the asylum to accommodate 300 patients was opened in 1895; the present hospital has accommodation for 200 patients. After the ceremony an address was delivered by Dr. Clouston, of Morningside Asylum, Edinburgh, who spoke at length on the modern treatment of the insane. Dr. Clouston remarked on the value of hospitals in connexion with asylums and claimed that the first building devoted to such a purpose was the one at Morningside. He expressed his gratification at the extension of this system, which had received the commendation of the Commissioners in Lunacy. The Hawkhead hospital seemed to him to combine all the scientific ideas which were known for the amelioration of the insane.

Important Prosecution under the Medical Act.

At Glasgow Sheriff-court, on July 8th Abraham S. Eastburn, who was alleged to call himself physician and surgeon, professor, American eclectic medical specialist, and using the letters A.M.S., was charged at the instance of the Scottish branch of the General Medical Council with having been guilty of an offence within the meaning of the Medical Act, 1858, in so far as during the month of June, 1898, he falsely pretended to be, and took, or used, the name or title of a physician, doctor of medicine, licentiate in medicine and surgery, or other names, titles, or descriptions, implying that he was registered under the Medical Act, or that he was recognised by law as a physician or surgeon, or a practitioner in medicine, whereby he had incurred a penalty not exceeding £20. Mr. R. P. Lamond appeared for the prosecution and Mr. A. S. D. Thomson, advocate, represented the respondent. Evidence was led for the prosecution. William M. Leitch, printer, produced specimens of bills which he printed for the respondent. He printed 20,000 of the large bills in the course of a year. A million of the small handbills were ordered at a time, but the delivery was spread over a long period. Robert Forrester deposed that he was handed one of the respondent's bills in Hope-street and that he took the name of the man who was delivering the bills. He also described the respondent's premises, which bore a large sign with the words "Consulting Rooms. Prof. Eastburn, A.M.S." James Robertson, solicitor, registrar to the Scottish branch of the General Medical Council, produced the Medical Register to show that the respondent's name was not in the official list. He said there was no such title as "A.M.S." granted by the universities or medical corporations in the United Kingdom. "M.S." was the recognised abbreviation for Master in Surgery. Members of the public had often directed his attention to the respondent's bills. The subject had also been brought before the General Medical Council, which decided unanimously to institute the present proceedings. In the end Eastburn was convicted and fined £20.

July 13th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Irish Medical Association.

THE Committee of Council met on July 5th and further considered amendments to clauses in the Local Government Bill which affect the medical profession.

The Health Exhibition, Dublin.

A meeting of the committee was held at the Institute of Civil Engineers of Ireland on July 4th, when the large number of English firms who had applied for and had been granted space was noted. The offer of Messrs. Henderson and Sons to lend plants and flowers for decorating the building was accepted with thanks.

The Ulster Medical Society.

The annual meeting of the Ulster Medical Society was held on July 7th in the Belfast Museum, Dr. Lindsay, the President, being in the chair. The reports of the secretary and treasurer were passed. These indicated that the society is in a most flourishing condition. There are 151 members and the attendance at the meetings showed an average each night of over 43. The balance in hand at present is £25 10s. The following office-bearers were elected for next session:—President: Dr. Joseph Nelson. Vice-Presidents: Dr. John Campbell and Dr. David Gaussen. Treasurer: Dr. John McCaw. Secretary: Dr. James Colville. Pathological secretaries: Dr. J. Lorrain Smith and Dr. Lynass. Librarian: Dr. Cecil Shaw. Council: Professor Byers, Dr. McKisack, Dr. Calwell, Dr. J. Walton Browne, Dr. E. C. Bigger, and Mr. W. G. MacKenzie.

The Death of Dr. David Johnston.

I regret to announce the death of one of the best known and most highly respected practitioners of Belfast—Dr. David Johnston, who died at his residence in that city on July 6th from cerebral disease, at the age of sixty-three years. A few years ago he fractured his patella and he was always slightly lame since that accident. Two years ago he had another fracture of a leg and since then he had practically retired from active practice. Dr. Johnston was born near Castledawson, in County Derry, in 1835, but at an early age he came to Belfast and entered Queen's College, where he was a most hard-working student. He graduated M.D. of Queen's University in 1866 and in the same year he became a Member of the Royal College of Surgeons of England. He shortly afterwards began practice in Belfast, where he spent the remainder of his life and where he had an extremely large *clientèle* amongst the working and middle classes, with whom he was a great favourite and by whom he was deeply respected for his skill, his care, and his unfailing kindness. He was one of the best accoucheurs of his day in Belfast. The funeral took place on July 8th, an immense concourse of medical *confrères*, friends, and former patients attending to show a last act of respect. He leaves a family of two sons and one daughter, his wife having died seventeen years before him.

Pauper Attendants in the Belfast Union Infirmary.

The Local Government Board have written to the Belfast Board of Guardians stating that their inspector, Mr. Agnew, has again informed them that the pauper attendants act as assistant nurses and not as cleaners only, and they wisely recommend the guardians to confer with their responsible medical officers on the subject, the Local Government Board being very properly opposed to paupers being allowed to attend on the sick.

Sale of the Omagh Infirmary.

At a meeting of the County Tyrone Infirmary Board (held on July 8th) a resolution was passed in favour of selling the old building to the post-office authorities.

The Laboratories at Queen's College, Belfast.

In the House of Commons on July 8th on a discussion of the vote of £136,976 to complete the sum for public works and buildings in Ireland Mr. Arnold-Forster pointed out that the item for Queen's College, Belfast, was part of an expenditure which had already been sanctioned for that place and he thought it was high time that laboratories in this College should be completed. That College was doing better work than any of the other Queen's colleges and it was turning out a large number of active men. The medical side of the College was increasing in importance and members every year.

Belfast Royal Hospital.

A special meeting of the corporation was held on July 11th to consider the proposed revised charter for the government of the new Royal Victoria Hospital. The principal alterations in the charter as agreed upon between the Board of Management of the Royal Hospital and the new Victoria Hospital are as follows: 1. The hospital is to be called "Royal Victoria" instead of "Royal" Hospital. 2. The qualification of life governors to remain as at present (subscription of £50), but the qualification of annual subscribers to be £2 2s. instead of £1 1s.; present life governors of the Royal Hospital retain their status as regards the new hospital. 3. Medical, surgical, and other official appointments to the hospital to be made by the board of management instead of as hitherto by the general committee. 4. The representatives of the medical and surgical staff on the general committee to be 5 instead of 2 members and one-fifth of the 60 persons elected to the general committee in addition to the life governors and honorary officers to be ladies. 5. The board of management to consist of the honorary officers, 5 annually elected members of the medical and surgical staff, the present life governors, with 15 life governors and 15 annual subscribers elected by the general committee; one-fifth of the

Digitized by Google

said life governors and annual subscribers if possible to be ladies and one-third of each class elected to retire annually. 6. The stated meetings of the general committee and board of management to be abolished and in lieu thereof meetings to be held at such times as either may respectively appoint, the quorum to be 7 instead of 12, and the board of management to have power to appoint committees as they may see fit. The management and direction of all matters having reference to the building of the new hospital, &c., is to be vested in a committee of the subscribers of the moneys for the new hospital until it is opened, when such committee shall cease to exist, and the annual meeting of the corporation is to meet in March. The charter, as amended and submitted to the meeting, was (some of those present dissenting) approved of.

Cork Medical Benefit Association.

A general meeting of the members of the Cork Medical Benefit Association was held on July 9th at the offices of the association, Marlborough-chambers, Mr. William Egan being in the chair. The chairman expressed his gratification at the large number of members present and was glad to be able to tell them that their membership roll was steadily increasing and that the work of the association was being conducted with great success. The secretary (Mr. H. J. Casey) then submitted a financial statement, which showed that as the result of the past six months' working the association had a total balance to their credit of £74 6*s.* 9½*d.* after meeting all claims.

July 13th.

PARIS.

(FROM OUR OWN CORRESPONDENTS.)

The Treatment of Strabismus.

AT the meeting of the Academy of Medicine held on July 5th M. Panas communicated some observations upon this subject. He said that the squinting eye was the one which deviated most from the line of vision. Nevertheless strabismus was only apparently unilateral. If the phenomena accompanying this condition were analysed in detail it would be found that the strabismus was always bilateral, and if it appeared unilateral that was because the patient only used the eye which was least affected and in overcoming the deviation of this one exaggerated the obliquity of the other. As for therapeutic measures M. Panas held that as the affection was bilateral so there must be a bilateral operation. In 230 cases M. Panas performed tenotomy of both internal recti and stretched them in addition, thus lessening their tendency to over-action. M. Panas never performs advancement, finding a simple tenotomy sufficient. In 220 cases he had never seen any over-correction, or if there were a little it was only temporary. Of 220 convergent cases of strabismus he had 190 in which the result was immediately successful. In those which were unsuccessful the result was not over-correction but under-correction. In 10 cases M. Panas rectified this by advancement of the antagonistic muscles and in every case with success.

Creasote in Pulmonary Phthisis.

At the same meeting of the Academy M. Savine said that the favourable action of creasote in tuberculosis was due, firstly, to its bactericidal action on the microbes which accompany the bacillus of Koch, such as streptococci, pneumobacilli, and the like; secondly, to its stimulating action on nutrition, so that the phagocytes which prey upon the bacillus of Koch are increased in number; and, thirdly, to its chemical action upon the toxins secreted by the tubercle bacillus. The patients to whose cases M. Savine referred were those suffering from pulmonary phthisis of the first and second degrees but were not cachectic. Creasote was administered (*a*) by hypodermic injections of a 15 per cent. solution in olive oil with sometimes the addition of a little myrtol or eucalyptol in a dose of 10 to 40 cubic centimetres; (*b*) by continuous inhalations of from 5 to 10 grammes of an alcoholic solution containing 33 per cent. of creasote; and (*c*) by the mouth, either in oil, milk, or as an emulsion, beginning with a dose of 40 drops and gradually increasing it to 300 drops in the twenty-four hours. M. Savine objects to the administration of creasote in capsules, pills or cachets, for such methods are, he considers, responsible for the various gastric disturbances which have been set down to creasote. It should always be administered in a considerable quantity of fluid and preferably at the same time as food.

The Operative Treatment of Cancer of the Rectum.

At the meeting of the Society of Surgery held on July 9th M. Quenu read a paper upon the operative treatment of rectal cancer, especially with regard to the removal of these growths by an abdomino-perineal route. M. Quenu had somewhat modified the conclusions which he had formerly laid before the society. He had given up Kraske's operation and now followed one of two methods—the perineal in cases where the growth did not extend further than 10 centimetres from the anus and in other cases the abdomino-perineal. M. Quenu considered that the operations of M. Gaudier and of M. Chalot were faulty in not carrying out complete asepsis during and after the operation and in causing a great loss of blood. His own method was as follows: first stage, opening the abdomen and ligature of the hypogastric arteries; second stage, liberation of the sigmoid flexure and formation of a left iliac anus; third stage, commencement of the freeing of the rectum; fourth stage, perineal extirpation. The preliminary ligature of the arteries resulted in a great economy of blood, and the following stages were very simple. In M. Quenu's opinion this method would be the one of the future, for it allowed the surgeon to remove the majority of growths with a minimum of risk.

The Treatment of Lead Colic by Injections of Artificial Serum.

At the meeting of the Society of Biology held on July 2nd M. Delearde gave an account of nine patients who had been treated in the hospital of Lille. Eight were white lead workers and the ninth was a plumber. They had all worked in the lead for about two years and some of them had already suffered from colic, constipation, muscular pains, and peripheral neuritis. The sole treatment adopted was the injection of large doses of artificial serum (Hayem's formula) under the skin of the abdomen. Only one injection was made and that a quantity of 500 c.c. This dose proved sufficient to entirely relieve all the patients except one who was particularly severely affected, and she had to have an injection of 1 litre in all given in two doses at an interval of one day. The serum had no action upon the paralyses, but it did away with the muscular pains, the constipation, the headache, and the vomiting. Relief was given in a far shorter time than by the old methods of treatment.

The Ninth Congress of Alienists and Neurologists.

The ninth Congress of French Alienists and Neurologists will be held at Angers from Aug. 1st to 6th, 1898. The subjects for discussion are as follows:—Monday, Aug. 1st: Post-operative Psychical Disturbances; Aug. 2nd: The Part played by Arteritis in the Pathology of the Nervous System; Aug. 3rd: Transitory Delirium from a Medico-legal Point of View.

The Biological Institute in the Rue Dutot.

M. Brebant, the architect of the Pasteur Institute, has just been charged with the designing of a large building to contain laboratories and other rooms necessary for the model biological institute about to be built in the rue Dutot, opposite to the Pasteur Institute. Some years ago the ground was bequeathed by an anonymous lady to the Administrative Council of the Pasteur Institute which undertook to build a hospital upon part of the site thus assigned. The works have just been begun and the foundations will soon be laid. The architect hopes that the new institute will be ready for opening before 1900. The expenses are provided for out of the donation of 2,000,000 francs made last year by the Baroness Hirsch. Two-thirds of this sum, or at most three-quarters, will be employed in the building and furnishing; the remainder of the money will be reserved as an endowment. The new institute, the plans of which were designed by the architect of the Pasteur Institute in collaboration with the professors of this institution, will be unique. In it there will be treated patients suffering from those affections which are the special study of Dr. Roux. The new institute, in common with the Pasteur Institute, will be under the direction of M. Duclaux, who has appointed M. Gabriel Bertrand as head of the laboratory of biological chemistry. The biological department of the Sorbonne will be ultimately transferred to the new building in the rue Dutot.

July 11th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The German Medical Practitioners' Association.

THE delegates of the German Medical Practitioners' Association (Deutscher Aerztevereins Bund) held their annual meeting on June 28th and 29th at Wiesbaden. The principal subject of discussion was the admission of women into the medical profession. Medical women are very rare in Germany, as they are not permitted to take a German qualification. The few that there are have obtained their qualifications abroad, principally in Switzerland, and are therefore regarded by the laws of Germany as unqualified practitioners. Lawyers are divided in opinion as to the possibility of women becoming qualified under the present laws. A very serious obstacle is, or at least has been, caused by the regulation that German medical students must pass the *Abiturienten-Examen* at a German gymnasium before beginning their medical curriculum and there has hitherto been no gymnasium where women were admitted, but this state of things is now altered as a women's gymnasium has been founded by private means in Berlin. The discussion at the Practitioners' Association was opened by Professor Penzoldt of Erlangen, who first of all described the position of medical practice by females in countries where they are legally recognised as qualified. America, he said, affords no precedent for Germany, owing to the great difference in the social conditions of both countries. In England female practitioners are wanted for the native population in India, where religious prejudices often prevent native women from consulting medical men. In Russia the relatively small number of medical men, especially in the vast country districts, has induced the Government to look for medical aid wherever it may be obtainable, and on this account medical women have been encouraged. In Switzerland, the El Dorado of women's emancipation, there are only 23 ladies actually engaged in medical practice; the others have left the profession. The Swiss university professors are of opinion that the female students come up to the average level, but that they hardly ever excel in either knowledge or dexterity. Women are not strong enough either for the fatigues of country practice or for the performance of some surgical and gynæcological operations, so that female practitioners must necessarily fail in the struggle for existence. Their advocates say that the treatment of the diseases of women and children ought properly to be in the hands of female practitioners, and cases are quoted where women through bashfulness have deferred consulting a medical man until their condition became hopeless, but the fact is that the female gynæcologists in actual practice hardly ever undertake more than gynæcological examinations and minor operations and generally call in medical men for serious cases and important operations. Medical practice by women would therefore not be of any advantage to their own sex, whilst their admission as qualified practitioners would be injurious to the medical profession which already suffers greatly from overcrowding and from the competition of quacks. It seems strange, Professor Penzoldt said, that the medical profession should be the first to be thrown open to women, considering that the necessary course of study is more arduous and prolonged than is the case in the other learned professions. To give women a fair trial they should be allowed to enter the dental or the pharmaceutical professions, where technical ability is more wanted than scientific training. Midwifery practice would also be greatly improved if women of the better classes could be induced to enter on that career. Professor Penzoldt finally summed up his conclusions as follows. The admission of women to medical practice would be (1) of no advantage to the sick; would be (2) injurious rather than beneficial to the medical women themselves; and would be (3) prejudicial to the universities and to the medical profession. When women are admitted to the practice of medicine they must equally be allowed to engage in all the other academic careers. An animated discussion followed Professor Penzoldt's speech, the general result being that the delegates present agreed with his views. The other subjects considered at the meeting were of minor interest.

The State Examination in Medicine.

The Imperial Statistical Office has recently published the results of last year's State examinations. There were 1295 medical students admitted to the examination, of whom 1079 passed within the regular time. The greatest number (179) were examined in Munich, 152 in Würzburg, and 139 in Berlin. Berlin, although resorted to by the largest number of students, thus holds only the third place in numerical order, the explanation being that the Berlin State examination is regarded as the most difficult in the empire. The highest commendation bestowed—*sehr gut*, i.e., very good—was, in fact, not given to any of the candidates in Berlin, while in Munich and Leipzig 14 candidates obtained it. The State examination was passed by 23 foreigners, of whom one was an Englishman and two were Americans.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Hospital Saturday Fund and the Sydney Hospitals.

SEVERAL of the regular subscribers to the Hospital Saturday Fund in Sydney complained that on applying for admission to the hospitals assisted by the fund they were questioned as to their financial position and given to understand that payment was expected, notwithstanding that they presented a letter certifying that they were subscribers to the fund and were unable to pay for medical attendance. The committee of the Hospital Saturday Fund called a meeting of its members and delegates representing the regular subscribers to consider the complaints. The committee considered the complaints well founded and wrote to the governing bodies of the hospitals urging them to accede to the claims of the regular subscribers to the fund that they should be admitted to any of the charities assisted by the fund without being catechised as to their financial position or subjected to pressure for payment direct to the hospital. The committee, in recommending the claims of the subscribers, pointed out that "the regular subscribers to this fund consist entirely of wage-earners, mostly of the artisan class, that they contribute per head as much as it is reasonable to expect from them in support of their hospitals, and that the aggregate contribution is more than sufficient to pay the full cost and maintenance and treatment of any proportion of the whole number likely to require hospital treatment. In proof of this, while the fund since its inception has distributed among the various local hospitals the sum of £12,500 it has been called upon to recommend only 125 applicants for admission to those hospitals, the contribution being equal to £100 for each case recommended." The matter was referred to a joint committee of the Sydney Hospital and the Prince Alfred Hospital and this committee unanimously reported that the request of the subscribers should not be acceded to. This report was adopted by the hospitals.

Tenure of Staff at Sydney Hospital.

At a recent meeting of the board of directors of the Sydney Hospital it was proposed that in order to provide for an equitable system of promotion among the junior members of the honorary medical staff it was desirable that members of the staff holding the rank of honorary medical officers should hold office for a limited number of years and that the number of years during which full honorary medical officers may hold office should not exceed 12, divided into two periods of 6 years. After discussion the motion was negatived by a large majority.

Position of the Staff at the Launceston Hospital.

The hospital at Launceston is a growing institution. Originally founded as a cottage hospital it has gradually increased in scope. The medical control of the hospital has, however, remained the same in the hands of paid officers—a medical superintendent and a resident medical officer. For a long time the medical practitioners in the city have been agitating for an alteration and for the appointment of an honorary staff. Some time ago an honorary staff was appointed, but it proved to be such in name only, the work being still done by the paid officers. The local branch of the British Medical Association recently sent a deputation to the hospital board, asking for a change in the system of medical supervision so as to bring it into harmony with the practice obtaining in other countries. The chairman of the board, in reply, pointed out that the hospital was worked under an Act of Parliament

Digitized by Google

and the board had no power to alter the arrangements, but it could recommend changes to be made by Parliament. The board would give every consideration to the views of the deputation, but the present system had worked well for the hospital in the past. The board was responsible for the expenditure and had control of the medical staff, and it did not care to retain the responsibility without the control. It does not seem probable that any change in the management will be made.

Site for Infectious Diseases Hospital, Melbourne.

It is almost certain that the site at the Yarra Bend Asylum Reserve will be adopted for the new Infectious Diseases Hospital, Melbourne. The neighbouring municipalities have withdrawn their opposition and the Board of Health has approved of the site.

Thirlmere Home for Consumptives, New South Wales.

The Committee of the Queen Victoria Consumptive Homes Fund in Sydney decided on May 5th that the Executive Committee should take over the Thirlmere Home and part of the grounds on a lease of two years as a temporary hospital for phthisical patients. The hospital will be maintained by subscriptions, by the interest accruing on the amount in hand, and the aid expected from the Government paying £1 for every £1 subscribed by the public.

New Out-patient Department for the Melbourne Hospital.

The committee of the Melbourne Hospital has definitely decided to erect a new out-patient department and recently waited on the treasurer to ask for Government assistance. The treasurer would not give a definite promise, but the committee is going on with the work. Meanwhile it is involved in a dispute with the Board of Health as to the plans, the board insisting on certain fire-escapes and other alterations involving a large additional expenditure.

Austin Hospital for Incurables, Melbourne.

Matters have not been working smoothly at the Austin Hospital for Incurable Disease (Melbourne) for some time past. The medical officer is in supreme control over the nurses, domestic and general arrangements, as well as the patients. This arrangement has not worked well and the committee has determined on a change. It has been decided to appoint a medical officer at a lower salary, whose duties will be confined to the patients; to appoint a matron with full control of the domestic arrangements, and a superintendent of nurses to be responsible for the nursing department. The resignation of the present medical superintendent, Mr. W. B. Norcott, has been accepted and he will be granted three months' leave of absence on full pay in recognition of his excellent services to the hospital during his six years' tenure, which the committee fully acknowledges.

St. Vincent's Hospital, Melbourne.

Some changes have been recently made in the honorary staff of this hospital. Dr. David Grant, M.A., has been appointed honorary physician to in-patients in place of Mr. P. Moloney, resigned; and Dr. Eustace Keogh has been promoted from the post of out-patient to in-patient physician in place of Dr. Riordan, resigned. Dr. Frank Newman has been appointed to Dr. Keogh's position and an additional out-patient physician has been appointed—Dr. J. H. McGee.

June 4th.

SOUTH WALES UNIVERSITY COLLEGE.—A meeting of the council of the South Wales and Monmouthshire University College was held on July 6th. A communication was read from the committee of the Glamorganshire and Monmouthshire Infirmary asking whether it was the intention of the College to complete at an early date the curriculum of the medical school. The council, although feeling that this was desirable, thought that owing to their financial position an endowment of at least £25,000 ought to be provided before they could establish a complete medical school on a sound basis. Professor Andrew Francis Dixon, B.A., M.B., B.Ch. (Trinity College, Dublin), was appointed dean of the medical faculty, and Mr. George Arbour Stephens, M.D., B.S., B.Sc. Lond., was appointed teacher in hygiene and physiology in the technical school.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen have passed the Second Examination of the Board in the subjects indicated:—

Wednesday, July 6th:—

Anatomy and Physiology.—Philip Lansdown Hickes, University College, Bristol, and Guy's Hospital; Hugh Dorsett Kempthorne, Ricardo Luis Jiménez, and Percy James Nash, Guy's Hospital; Richard Griffith, Cambridge University, London Hospital, and Mr. Cooke's School of Anatomy and Physiology; Edward Newbury Thornton, Philip Anthony Green, and Christian Parker, London Hospital; George Dewick, St. Thomas's Hospital and Mr. Cooke's School of Anatomy and Physiology; Charles Woolmer Davies, Archibald Edward Hill, and Robert H. William Garle, St. Thomas's Hospital; Francis Grey Bennett, Cambridge University and University College, London; Gordon Herbert Hackney, University College, London; Percy Reginald Fort and Henry Tregellas Doble, St. Mary's Hospital; Edward Lister Martin, Henry E. Gaskin Boyle, Maitland Bodley Scott, and George Harvey Low, St. Bartholomew's Hospital; Alfred Mason and Fred Bailey Penfold, Middlesex Hospital.

14 gentlemen were referred in both subjects.

Thursday, July 7th:—

Anatomy and Physiology.—Alfred Sheppard Grimwade, Melbourne University and St. Thomas's Hospital; Thomas W. Hardwick Downes and John Walker, St. Thomas's Hospital; William Morton Robson, Stanley S. Howard Shannon, Reginald Prynne Marshall, G. Brooke Forbes Churchill, and Francis M. Maxwell Ommanney, Guy's Hospital; Alfred John Courzens, Charles Leonard Traylen and Francis Inman Trimmer, London Hospital; Walter Gray Paget, George Mervyn Seagrove, Cyril Evelyn Hogan, Leslie Edward Hughes, and Verner George Heseltine, St. Bartholomew's Hospital; George William Curtis, Godfrey Faussett Rugg, and Frank Elliott Bolton, University College, London; James MacBain Ross, Melbourne University and St. Mary's Hospital; John Conrad G. Kunhardt, St. Mary's Hospital; Adrian R. Fortescue Hubbard, Charing-cross Hospital; Lancelot Walter Shadwell, St. George's Hospital; and Graham Pallister Young, King's College, London.

11 gentlemen were referred in both subjects.

Friday, July 8th:—

Anatomy and Physiology.—Francis Curthbert Jobson, Westminster Hospital; Robert Markham Carter, William Edward Houlbrook, Keppel Hart-Reeds, John W. Smyth Seccombe, St. George's Hospital; Thomas Scarbrough Dudding, London Hospital; John Henry Wroughton, Victor John Duigan, St. Bartholomew's Hospital; Sidney H. Charles Bent and Frank Wybourne Smith, Guy's Hospital; Ernest Edward Semmence, Edinburgh University and St. Thomas's Hospital; Walter F. Hamilton Vaughan, George Ralph Cox, and Eric Craiger Lindsey, St. Mary's Hospital; and Edwin Augustus Houchin, Middlesex Hospital.

16 gentlemen were referred in both subjects.

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates at the primary examination have passed in the subjects indicated:—

PART I.

Biology.—A. B. Gosse; E. M. Handley, Royal Free Hospital; and M. S. Jevons.

Chemistry.—G. M. Crockett and K. A. Dawson, Royal Free Hospital; A. B. Gosse; M. E. Martin and F. Murray, Royal Free Hospital; W. A. C. Niven; A. U. Parkhurst, Cardiff; T. G. Prosser and L. G. Simpson, Royal Free Hospital; and A. Whitby, Dublin.

Materia Medica and Pharmacy.—K. A. Dawson, Royal Free Hospital; L. Demergue, Paris; L. Denny, Royal Free Hospital; P. T. Goodman, St. Thomas's Hospital; R. A. Lyster and F. H. Maberly, Birmingham; C. J. Marsh, University College Hospital; C. G. Meade, St. Bartholomew's Hospital; H. R. Miller, Guy's Hospital; F. Murray, Royal Free Hospital; A. U. Parkhurst, Cardiff; L. K. Tickner, Durham; and A. Whitby, Dublin.

PART II.

Anatomy.—H. H. Beale, St. Mary's Hospital; A. E. Brown, Royal Free Hospital; P. J. R. Bucknill, Manchester; P. C. Burgess, Middlesex Hospital; T. M. Burton, Royal Free Hospital; E. N. de V. Dawson, St. Thomas's Hospital; S. de Carteret and C. D. A. Dowman, St. Bartholomew's Hospital; E. A. Dunn, Royal Free Hospital; J. C. Furness, Charing-cross Hospital; A. E. Gilford, R. Gillett, H. M. O. Jones, and D. E. Lockwood, Royal Free Hospital; C. L. Mandl, Edinburgh; L. S. Molony and F. M. Payne, Royal Free Hospital; W. Roper, Edinburgh; P. G. Sheppard, Cambridge and Liverpool; A. D. Sibree, Royal Free Hospital; P. S. Stokes, Sheffield; M. E. Unwin, Royal Free Hospital; and G. H. Watson, St. Bartholomew's Hospital.

Physiology.—J. M. Anderson, Aberdeen; A. E. Brown, Royal Free Hospital; P. J. R. Bucknill, Manchester; T. M. Burton and E. Courtauld, Royal Free Hospital; E. N. de V. Dawson, St. Thomas's Hospital; S. de Carteret and C. D. A. Dowman, St. Bartholomew's Hospital; E. A. Dunn, Royal Free Hospital; B. M. Dunstan, St. Thomas's Hospital; A. B. Edwards, St. Bartholomew's Hospital; J. C. Furness, Charing-cross Hospital; A. E. Gilford, R. Gillett, H. M. O. Jones, and D. E. Lockwood, Royal Free Hospital; C. L. Mandl, Edinburgh; L. S. Molony and F. M. Payne, Royal Free Hospital; A. F. Reardon, St. Thomas's Hospital; W. Roper, Edinburgh; P. G. Sheppard, Cambridge and Liverpool; A. D. Sibree, Royal Free Hospital;

P. S. Stokes, Sheffield; L. K. Tickner, Durham; M. E. Unwin, Royal Free Hospital; G. H. Watson, St. Bartholomew's Hospital; A. Whitby, Dublin; and F. E. D. Woodroffe, Edinburgh.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following gentleman having passed the necessary examination has been admitted a Fellow of the College:—

Thomas Hennessy, L.R.C.S., L.R.C.P. Irel.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.—At a stated meeting of the College, held on July 8th, the following gentlemen were admitted:—

As Member.—R. Travers Smith, M.D. Dub.
As Licentiate.—A. Cooper Fenn, L.S.A.

FOREIGN UNIVERSITY INTELLIGENCE. — *Chicago (Rush Medical College):* Dr. Henry Baird Favill has been appointed Professor of Experimental Therapeutics. *(Medical College):* Dr. A. R. Edwards has been appointed Professor of Medicine.—*Lyons:* Dr. Bordier has been appointed after public competition *professeur agrégé* of Physics in the Medical Faculty. Dr. Sambuc has been similarly appointed *professeur agrégé* of Chemistry. — *Montpellier:* Dr. Bertin-Sans has been appointed after public competition *professeur agrégé* of Physics.— *Naples:* Dr. Nicola Furgiuele has been recognised as *privat-docent* of Operative Medicine, Dr. Barucco and Dr. Michele de Amicis as *privat-docenten* of Dermatology and Syphilography, Dr. E. de Arcangelis as *privat-docent* of Forensic Medicine, and Dr. Luigi Maramaldi as *privat-docent* of Materia Medica and Pharmacology.—*Paris:* Dr. E. A. Broca has been appointed after a public competition *professeur agrégé* of Physics in the Medical Faculty.—*St. Petersburg (Military Medical Academy):* Dr. M. P. Manassein and Dr. S. T. Kulneff have been recognised as *privat-docenten* of Dermatology and Syphilography.—*Toulouse:* Dr. Gérard has been appointed after public competition *professeur agrégé* of Pharmacy.—*Turin:* Dr. Umberto Monari has been recognised as *privat-docent* of Surgery.—*Vienna:* Dr. Julius Scheff has been appointed Extraordinary Professor of Odontology. — *Warsaw:* Dr. Ushinski has been appointed Ordinary Professor of General Pathology.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—The following have been elected officers and council of the society for the season commencing October, 1898. President: Dr. R. Fortescue Fox (Strathpeffer Spa). Vice-Presidents: Dr. Frederic Bagshawe (St. Leonards-on-Sea), Dr. R. O. Gifford Bennet (Buxton), Mr. Robert Cuffe (Woodhall Spa), Mr. W. Bowen Davies (Llandrindod Wells), Dr. J. Ivor Murray (Scarborough), Dr. Charles Parsons (Dover), Dr. Samuel Hyde (Buxton), Dr. Henry Lewis (Folkestone), Dr. Andrew S. Myrtle (Harrogate), Dr. J. G. Douglas Kerr (Bath), Dr. George Oliver (Harrogate), and Dr. W. V. Snow (Bournemouth). Council: Mr. Walter C. Blaker (Bognor), Dr. Morgan Dockrell (London), Dr. R. Eardley-Wilmot (Leamington), Dr. W. Black Jones (Llangammarch Wells), Dr. H. Laing-Gordon (Forest-hill, S.E.), Dr. John Inglis (Hastings), Dr. C. G. Havell (Felixstowe), Dr. William Haldane (Bridge-of-Allan), Dr. Edmund Hobhouse (Brighton), Dr. John Hackney (Hythe), Dr. Joseph G. Harsant (Bournemouth), Mr. Alfred Haviland (Douglas), Dr. W. Maccall (Southport), Dr. J. Perrott Prince (Natal), Dr. Thomas Macqueen (Eastbourne), Dr. Henry McClure (Cromer), Dr. Patrick Letters (Valencia), Dr. Abraham Thomas (Aberystwith), Dr. W. Moxon (Matlock), Dr. A. W. Orwin (London), Dr. Reginald Pollard (Torquay), Dr. Ernest Solly (Harrogate), Dr. Alfred F. Street (Westgate), Dr. C. H. Tamplin (Ramsgate), Dr. Alexander Thom (Crieff), Dr. C. W. E. Toller (Ilfracombe), Dr. W. J. Tyson (Folkestone), Dr. Leonard Williams (London), Mr. H. H. Ward-Humphreys (Cheltenham), and Mr. George S. Watson (Tunbridge Wells). Chairman of Council: Dr. Samuel Hyde (Buxton). Honorary treasurer: Mr. C. R. B. Keetley (London). Librarian: Dr. Morgan Dockrell. Honorary secretaries: Mr. H. Shirley Jones (Droitwich) and Dr. Septimus Sunderland (London).

BRUSSELS MEDICAL GRADUATES' ASSOCIATION.—The annual general meeting of this association was held at the Café Royal, Regent-street, on Tuesday, July 12th. Dr. A. W. Thomas was elected President for the year in succession to Dr. C. T. Brookhouse, and Dr. Younger and Dr. Major Greenwood were re-elected to their respective posts of treasurer and honorary secretary. The following gentlemen were also elected members of Council: Dr. Gabe, Dr. Achard, Dr. Snape, Dr. Naumann, Dr. Wunderlich, Dr. Haydon, Dr. Eady, Dr. Walter Smith, Dr. Edwards, and Dr. Vicars. Dr. Charles Burland was elected vice-president and the honorary secretary on presenting the balance sheet pointed out the satisfactory financial condition of the association and its general progress. After the meeting the members and their friends, to the number of sixty, dined together and spent a very pleasant evening. Dr. F. Roberts, Dr. Heron, Mr. Joseph Smith, Mr. George Brown, Dr. Clement Godson, Mr. Howard Marsh, and Dr. Morgan Dockrell were among the guests. The musical programme was furnished by Madame Minnie Hatch, Miss Rhoda Whiley, and Mr. Stanley Verde, assisted by Dr. Arthur Haydon, who played some admirable violin solos; Dr. Roberts also contributed to the entertainment by singing several songs in his usual excellent manner.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Karl Freiherr von Rokitansky, Professor of Gynæcology in the University of Gratz, on June 21st, aged fifty-nine years. He was the third son of the great pathologist and was for some years attached to the Vienna school as *privat-docent*.—Dr. Karl Edward With, formerly Professor of Clinical Medicine in Copenhagen, aged seventy-two years. He gave up his post about four years ago. His medical writings were chiefly on the subject of heart diseases and diseases of the stomach and intestines.—Dr. Maieff, *privat-docent* of Syphilography in the Military Medico-Chirurgical Academy of St. Petersburg.—Dr. Friedrich Albert von Zenker, formerly Professor of Pathological Anatomy in the University of Erlangen, on June 13th at Reppentin in Mecklenburg, where he was on a visit. He was seventy-three years of age. In early life he had been assistant to Radius in Leipsic and to Rokitansky in Vienna. He went as Professor to Erlangen in 1862 and only retired three years ago. He, together with Professor Ziemssen, founded the well-known *Archiv für Klinische Medicin* in 1865.—Dr. Franz Kretschy of Vienna, who was for some time assistant to the late Professor Bamberger.

THE ADMINISTRATION OF ADDENBROOKE'S HOSPITAL.—At the invitation of a special committee appointed to inquire into the administration of Addenbrooke's Hospital Sir Henry Burdett has made a careful investigation and prepared a report which was presented at the quarterly court held on June 27th. The subjects chiefly considered were the constitution, the expenditure, and the income of the hospital. Sir Henry Burdett's first recommendation is that a selection committee for the purpose of appointing the honorary medical officers of the hospital be set up at the first general court in each year and that it consist of 50 governors, 18 of whom shall be the members of the committee of management subsequently referred to, 8 the honorary physicians and surgeons for the time being, and 24 other governors—namely, 8 from each of the three groups of governors representing respectively the county, the borough, and the university. It is further suggested that a new by-law should be passed providing that any candidate who directly or indirectly canvasses the governors shall be disqualified. Another recommendation is that in lieu of the open weekly board of governors as at present existing, which any governors who please may attend and vote at, there should be appointed a committee of management, consisting of, say, 18 lay governors, with some or all of the physicians and surgeons, who collectively number 8, one-third of the members of this committee to retire every year, but to be eligible for re-election. With regard to the expenditure Sir Henry Burdett is of opinion that if the governors err at all they err, and have erred for some years, not in the direction of over-expenditure, but of under-expenditure. The cost of provisions, including the board of both patients and staff, has for the last three successive years been 6*s.* 4*d.*, 6*s.* 1*d.*, and 6*s.* 2*d.* per head per week. During each of these same three years the income of the hospital from all sources, including legacies, has exceeded the total ordinary and extraordinary expenditure. Sir Henry Burdett is confident that it would tend to promote economy, to increase the income, and to place the hospital administratively in a strong position if a resident superintendent were appointed at a salary of, say, £250 per annum with board and residence. He should be charged with the general administration of the institution, the supervision and purchase of stores, and the general discipline of the household so far as the male servants are concerned.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ELECTION OF PRESIDENT.

A QUARTERLY meeting of the Council was held on July 14th, the President, Sir WILLIAM MACCORMAC, being in the chair. The election of President took place at the close of business and resulted in the re-election of Sir William MacCormac, Mr. T. Pickering Pick and Mr. Howard Marsh being appointed Vice-Presidents.

BEQUESTS AND DONATIONS TO HOSPITALS.—The trustees of the late Mr. Richard Gibbs have contributed out of his estate £1000 to St. Thomas's Hospital to endow a bed in memory of the deceased. — The committee of the Alexandra Hospital for Children with Hip Disease, Bloomsbury, has received £203 3*s*., Mrs. Raphael's collection.—The treasurer of the Royal Sea-bathing Hospital, Margate, has received from the executors of Miss Marter £168 7*s*. 1*d*.—The members of the London Metal Exchange have contributed £788 to the London Hospital as a donation to its funds.—The late Mr. John Bennett of Bristol has bequeathed £500 to the Bristol Hospital for Sick Children and Women and £1736 each to the Bristol Royal Infirmary and Bristol General Hospital. — The treasurer of the Scarborough Hospital and Dispensary has received £250, a legacy bequeathed by the late Dr. Vandyke Carter of Scarborough.—An anonymous donor of £1000 has endowed the Kingsley bed in perpetuity at St. Thomas's Hospital, London, in memory of the late Rev. Charles Kingsley of Eversley.—The treasurers of the Middlesex Hospital have received £105 from the Worshipful Company of Drapers; also £250 from the Goldsmiths' Company; also £105 from the Mercers' Company; also £100 from the Grocers' Company; also £300 from the trustees of Smith's (Kensington Estate) Charity.—The Baroness Hirsch has contributed £100 to the Queen Charlotte's Lying-in Hospital, Marylebone-road, London. The committee of the same institution has received a donation of £105 from Messrs. J. S. Morgan; also £100 from the trustees of Smith's (Kensington Estate) Charity.—The council of the Chelsea Hospital for Women, Fulham-road, has received £1000 bequeathed by the late Mrs. E. H. Harris.—The committee of the Royal Ophthalmic Hospital, Moorfields, London, has received £900 bequeathed by the late Mrs. E. H. Harris; also £100 from Smith's (Kensington Estate) Charity; also £703 7*s*. 2*d*. from the trustees of the late Miss Helen E. Furner; also £100 from Messrs. C. Hambro and Sons.—The committee of the North-Eastern Hospital for Children, Hackney-road, Shoreditch, has received £600 from the Goldsmiths' Company.—The treasurer of the Italian Hospital, Queen-square, Bloomsbury, has received £503 17*s*. 8*d*., the result of the ball held in May last at the Royal Institute of Painters in Water-colours, Piccadilly.—The committee of the Hospital for Diseases of the Throat, Golden-square, London, has received £1000 from the executors of the late Mrs. E. H. Harris and £100 from the executors of the late Mr. H. L. Beddington.—Mr. Herbert J. Allcroft has contributed £105 to the St. Mary's Hospital, Paddington.—Lord Iveagh has given a donation of £1000 to the Endowment Fund of the Eastern Counties Asylum for Idiots.—The committee of the London Fever Hospital, Liverpool-road, Islington, has received from the London Corporation £105 and from the trustees of Smith's (Kensington Estate) Charity £200.—The treasurer of Guy's Hospital has received from Sir James Blyth, Bart., £105.—The committee of the North London Hospital, Gower-street, London, has received a legacy of £421 10*s*. 3*d*. from Mrs. Lecky's trust; also legacies of £90 from Mr. H. L. Beddington and of £6000 from Mrs. E. H. Harris; also a donation of £1200 from Mrs. C. Horsley to found a bed in remembrance of her brother, John P. Potter; also £300 from the trustees of Smith's (Kensington Estate) Charity.—The treasurer of St. Mark's Hospital, City-road, London, has received £1000 from Mrs. D. Henty to endow a bed to be called the "Julia Henty Bed."—The committee of the Great Northern Central Hospital, Holloway-road, N., has received £400 from the trustees of Smith's (Kensington Estate) Charity; also £100 from the Goldsmiths' Company; also £125 from Mr. T. Braithwaite, jun., being the second half of his promised contribution of £350.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Habitual Inebriates Bill.

THIS Bill passed through the Grand Committee with very few alterations. On the motion of Mr. PICKERSGILL a proviso was inserted in Clause 4 to the effect that no regulation of the Secretary of State with regard to the proposed State inebriate reformatories shall authorise the infliction of corporal punishment, and on the motion of the Home Secretary the scope of the Bill was extended to Ireland instead of being confined to England and Scotland as originally proposed.

The Poisons Bill.

Mr. BALFOUR intimated in the course of a statement about the business of the session that the Government will not proceed further with the Poisons Bill during the present session.

Vaccination Bill.

The following is the proposed new clause framed by Sir WALTER FOSTER in view of the report stage of the Vaccination Bill, viz.:—

Where a child is by this Act required to be vaccinated within six months after the birth of the child the parent or person having the custody of the child may, not less than two months before the expiration of six months from the birth of the child, make a statutory declaration of conscientious objection to the vaccination of the child, and if the statutory declaration is within seven days after its date delivered to the registrar of births for the district in which the child resides the registrar shall register the same and shall if required deliver to the parent or other person making the declaration a certificate of such registration and shall also send a copy of the certificate to the public vaccinator of that district, and thereupon an order shall not be made or proceedings taken with reference to the non-vaccination of the child mentioned in the certificate.

The Amendment of the Pharmacy Acts.

The Government has given an undertaking to introduce into the Bill for the amendment of the Pharmacy Acts a provision dealing with the case of companies which carry on the business of drug stores free from any of the restrictions imposed upon members of the Pharmaceutical Society.

HOUSE OF COMMONS.

THURSDAY, JULY 7TH.

Indian Medical Service.

Captain NORTON asked the Secretary of State for India if he would inquire from the Government of India whether any, and if so what, proposals or recommendations had been made as to prolonging the period of Indian Medical Service Officers in Principal Medical Officers' offices to enable them to acquire a sufficient knowledge of military duties before their promotion to administrative military appointments after long years of employment in civil medical billets.—Lord GEORGE HAMILTON replied that the Government of India would forward to him any recommendations they considered necessary or likely to improve the general efficiency of the medical service, and he saw no reason for making the inquiry suggested.

Army Medical Service.

Captain NORTON asked the Under-Secretary of State for War what was the exact strength of army medical officers required for two army corps, this strength to include the number of army surgeons of all ranks required on the staff for bearer companies, for field, stationary, and general hospitals, and hospitals on the line of communications.—Mr. BRODRICK replied: Two army corps would require 226 medical officers, including administrative ranks; but this does not include the line of communications. The stationary and general hospitals would form a part of the line of communications. A stationary hospital of 100 beds has 4 medical officers, and a general hospital of 520 beds has 20. The number of these hospitals would depend on the length of the line, the climate, and the nature of the campaign.

The Bullets for the Soudan.

Mr. DILLON asked the Financial Secretary to the War Office, whether a special bullet had been manufactured to be used by the British troops in the Khartoum expedition; if so on what grounds had it been found necessary to supply the troops with a special bullet, and whether the War Office had had any medical report as to the effect of the bullet on animals before allowing it to be used in war.—Mr. POWELL WILLIAMS replied that no special bullet had been manufactured for use in Egypt. The bullet sent was that which had been adopted for general use in the army after experiment and medical report.—Mr. SWIFT MACNEILL asked whether it was the Dum Dum bullet.—Mr. POWELL WILLIAMS replied in the negative.

Asylum Accommodation in London.

Sir MANCHERJEE BHOWNAGGREE asked the President of the Local Government Board if he was aware that on account of insufficient accommodation for imbecile children suffering from epilepsy the guardians of the parish of St. Matthew, Bethnal-green, were recently obliged to admit an imbecile child so afflicted into a private lunatic asylum; that the Middlesex County Asylum on being applied to previously had refused to receive this case owing to the overcrowded state of that asylum; and if so, whether it was intended to take any immediate steps with a view to provide sufficient accommodation for such cases.—Mr. CHAPLIN replied: I have made inquiry into this matter and I learn that the boy referred to is eight years of age, that he was formerly an inmate of the Darenth Asylum but was removed by his parents, and that when subsequently admitted to the Bethnal-green workhouse, the guardians found a difficulty in obtaining accommodation for him either at the asylums of the Metropolitan Asylums Board or of the Asylums Committee of the London County Council and he has been sent to the Hoxton Licensed House. The managers of the Metropolitan

Digitized by Google

Asylums District are considering the question of additional provision and I understand that the London County Council are providing additional accommodation.

FRIDAY, JULY 8TH.

River Pollution in East London.

Mr. ERNEST GRAY asked the President of the Local Government Board whether his attention had been drawn to the condition of that part of the Channelsea River which lies within the county borough of West Ham; whether he was aware that under certain conditions of tide and of weather this water is little better than an open sewer and therefore dangerous to the public health; also that for several years a conflict of opinion has existed between the Lea Conservancy and the several local sanitary authorities as to the responsibility for the pollution of the river; and whether, having regard to the serious annoyance and dangers arising from the present condition of these waters, he could take any steps to have the local responsibility determined and satisfactorily discharged.—Mr. CHAPLIN replied: I believe that the facts are practically as stated in the question, but the powers of the Local Government Board are very limited in this matter and I have no authority to determine the local responsibility. I am alive, however, to the fact that the present condition of affairs is very far from satisfactory and I am taking such measures as I can to bring about an improvement. I may add that the corporation are disinfecting the Channelsea daily and they promoted a Bill this session which would have given them absolute authority to cleanse and scour the river, but the preamble was held not to be proved.—Mr. GRAY asked whether the right hon. gentleman would consider the advisability of having a public inquiry.—Mr. CHAPLIN said he had already instructed one of the inspectors of the Board to visit the locality and make a report, and in the first instance he should like to see what he had to say about the matter.

MONDAY, JULY 11TH.

Vaccination Questions.

The two following questions appeared on the notice paper, viz.:—Mr. CHANNING: To ask the President of the Local Government Board whether in the case of the child Frederick Edwards, whose death has been found by a coroner's inquest in Southwark to have been caused by erysipelas set up by vaccination, this child was vaccinated by Dr. Cory, superintendent of the National Vaccine Establishment, Lamb's Conduit-street; whether the lymph used was glycerinated calf-lymph and similar to that used in the case of the child Annie Little in Battersea, whose death was recently found by a coroner's inquest also to be due to erysipelas set up by vaccination; whether it has been brought to his notice that Dr. Cory, although requested to attend the inquest by the coroner, Mr. Langham, failed to attend; and, what steps he proposes to take in reference to Dr. Cory and to prevent the use of lymph which has produced these fatal results.—Mr. STEADMAN: To ask the President of the Local Government Board whether he is aware that a death occurred on June 20th, at 17, Railway-approach, London-bridge, from erysipelas following vaccination by Dr. Cory at the National Vaccine Establishment on May 24th; whether he is aware that Dr. Cory did not attend the inquest although the coroner's officer is reported to have said that he had written to Dr. Cory telling him the time of the inquiry; and whether he will give instructions that a public inquiry shall be made into all the circumstances connected with this death.—Mr. CHAPLIN, rising in his place when the first question was put from the chair, said: The hon. Member is not here to ask this question, but it is in the public interest, I think, that it should be answered and I therefore desire to answer it and also the question of the hon. Member for Stepney at the same time The child in question was vaccinated as stated by the superintendent of the National Vaccine Establishment on May 6th. The lymph used was not glycerinated calf-lymph, the child being vaccinated with 12 other children at the same time from the same calf, from calf to arm. The 13 children were inspected seven days afterwards, on May 31st, and in all of them the vaccination had followed the normal course and it was not until twenty days after vaccination that the child was brought again to the station and found to be suffering from erysipelas. The ordinary period of incubation of erysipelas is from one to three days and the period which elapsed between vaccination and the appearance of erysipelas shows that the erysipelas was due not to the lymph, but to secondary infection during the third week after vaccination. Dr. Cory was not requested to attend the inquest. He was informed that an inquest would be held on June 30th at an hour when he had to vaccinate a large number of persons, and he therefore on the 29th visited Dr. Burke, who had attended the child, and gave him all the information he possessed as to the case. As a public inquiry has been held by the coroner, who is reported to have stated to the jury that there was no evidence that the child died from erysipelas set up by vaccination, thus confirming the information which I have received, I do not see the necessity for a further inquiry.

Cost of the Brook Hospital.

Dr. FARQUHARSON asked the President of the Local Government Board if he had had his attention called to a discrepancy of £70,000 between the estimate of the architect for the Brook Hospital and the final cost of this building; and if he would consent to supply the House with a return showing the actual cost of each of the hospitals of the Metropolitan Hospitals Asylum Board in comparison with the original estimate for the same.—Mr. CHAPLIN replied: Yes, sir, there is a large discrepancy, amounting to upwards of £60,000, between the estimate of the architect and the cost of the hospital buildings, and the subject is receiving my attention. If the hon. Member gives notice of motion for a return I will consider the propriety of granting it.

Unsound or Diseased Foreign Meat.

Mr. FIELD asked the President of the Local Government Board to explain why no prosecution could follow a person or property from a foreign company consigning unsound or diseased meat into this country; and whether he could arrange that legal penalties would ensue to importers similar to those inflicted on native producers under like circumstances.—Mr. CHAPLIN replied: When meat has been seized on the ground of its being diseased or unsound the person to whom the same belongs or did belong at the time of exposure for sale, or in whose possession or on whose premises the same is found is liable to a penalty, or may, at the discretion of the justices, be sentenced to imprisonment without the option of a fine. This provision applies equally to unsound or diseased meat, whether imported from abroad or native produce, and there is no exemption in the case of meat sent to this country by a foreign company.

Experiments on Living Animals.

Mr. JOHN ELLIS asked the Home Secretary what were the severer measures which he stated had been taken in respect of the persons who were reported by the inspector as having committed breaches of the Cruelty to Animals Act, 1876, by performing painful experiments on living animals without the necessary licences or certificates.—Sir M. WHITE RIDLEY: Temporary suspension of, and refusal to renew, licences.—Mr. ELLIS asked the right hon. gentleman whether he could state or lay upon the table the terms of the conditions and regulations attached by the Home Office to the licences and certificates granted to persons for the performance of painful experiments of living animals under the Cruelty to Animals Act, 1876.—Sir M. WHITE RIDLEY: The conditions are not always the same, but may vary according to the nature of the investigation. It is hardly possible, therefore, for me to state all the conditions attached to licences and certificates. The most important conditions, however (besides the limitations as to place, time, and number of experiments), and the conditions most frequently imposed are those as to reporting and the use of antiseptics. The latter condition is that the animals are to be treated with strict antiseptic precautions, and if these fail and pain results they are to be killed immediately under anæsthetics. The reporting conditions are, in brief, that a written record in a prescribed form is to be kept of every experiment and is to be open for examination by the inspector; that a report of all experiments is to be forwarded to the inspector; and that any published account of an experiment is to be transmitted to the Secretary of State. Another condition requires the immediate destruction under anæsthetics of an animal in which severe pain has been induced after the main result of the experiment has been attained.—Mr. SWIFT MACNEILL asked whether it was the case that since the Act was passed in 1876 there had never been a public prosecution under it.—Sir M. WHITE RIDLEY: I am not aware of it.—Mr. SWIFT MACNEILL: Well, I am.

TUESDAY, JULY 12TH.

Manchester Prison Case.

Mr. FLOWER asked the Home Secretary whether his attention had been called to the case of an insane prisoner named Edward Cox, confined in Manchester prison; and whether it was a fact that the prisoner had seven and probably eight of his ribs broken, that the medical inspector sent down to inquire into the case reported that only one of the man's ribs had been broken, while Mr. Dickinson, a London stipendiary magistrate, after a special inquiry arrived at the conclusion that seven or eight of the prisoner's ribs were broken, and, if so, what action he had taken with regard to the medical inspector.—Sir M. WHITE RIDLEY replied that he answered a question on this case in March last. The medical inspector had no opportunity of examining the prisoner until seven days after the injury. The prisoner was then still strapped up and as removal of the strap was thought to be inexpedient and the prisoner was unable to give any rational account of his injuries it was impossible for the inspector to ascertain what the extent of the injury had been. His report was that he was not convinced that more than one, or at most two, ribs were broken. In these circumstances he (Sir M. White Ridley) did not consider that any blame attached to him for failing to discover the full extent of the injury.

Venereal Disease in India.

Mr. JAMES STUART asked the Secretary of State for India whether a letter had been issued under date Nov. 20th, 1897, by the Government of India, Military Department, purporting to state explicitly the policy of the Government of India with respect to the future treatment of venereal disease in cantonments, stating that among other things medical officers might make arrangements to carry out from time to time the examination of women who voluntarily present themselves; and whether the statement of policy made in that letter had been sanctioned by him.—Lord GEORGE HAMILTON: The instructions issued by the Government of India in the letter to which the hon. Member refers are based on my despatch No. 25 of March 26th, 1897, which has been presented to Parliament, and I see no reason to question their propriety.

The Superannuation of Irish Medical Officers.

Mr. PATRICK O'BRIEN asked the Chief Secretary to the Lord Lieutenant of Ireland whether his attention had been called to the case of Mr. R. B. Moore of Rockcorry, county Monaghan, who, at the age of seventy-five years and after serving forty-four years as dispensary medical officer, when obliged to retire through ill-health, was refused any superannuation; and whether, in view of such a case as this and the possibility of other similar cases, he would consider the advisability of accepting some of the amendments on the paper to the Local Government (Ireland) Bill making it compulsory on the new local bodies to grant superannuation.—Mr. GERALD BALFOUR: I am informed that the proposal to grant a retiring allowance to Mr. Moore has been twice before the guardians but that it fell through on both occasions. I could not undertake in the Local Government Bill to deal with the general question of superannuation of officers.

Appointments.

Successful Applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ALEXANDER, J., M.D. Durh., L.R.C.P., L.R.C.S. Edin., D.P.H. Glasg., has been appointed Medical Officer of Health for the Burgh of Thurso.

ANCRUM, GEORGE WAYLAND, M B., C.M. Edin., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Honorary Assistant Surgeon for the Gloucester General Infirmary.

NOTTINGHAM GENERAL DISPENSARY.—Senior Resident Surgeon. Salary £170, with furnished rooms. Also Clinical Assistant for six months. Salary £60 for that period, with furnished rooms. Each has to pay one-third of the maintenance of the housekeeper and servant, whose wages are paid by the Committee.

OWENS COLLEGE, Manchester.—A Senior and Junior Demonstrator in Physiology. Stipends £150, rising to £200, and £100, rising to £150. Also an additional Demonstrator of Anatomy for the ensuing winter session.

ROYAL HALIFAX INFIRMARY.—Assistant House Surgeon, unmarried. Salary £50 per annum, with an extra allowance of £9 2s. 6d. per annum. An Ophthalmic Department has been recently added to the general practice of the Infirmary. Also residence, board, and washing.

ROYAL SEA-BATHING HOSPITAL, Margate.—Resident Surgeon. Salary £100 per annum, with board and residence. Applications to the Secretary, Royal Sea-bathing Hospital Offices, 30, Charing-cross, London.

SALISBURY INFIRMARY.—Assistant House Surgeon for six months. Honorarium of £10 will be given conditionally. Board, lodging, and washing provided.

SHAFTESBURY HOUSE PRIVATE ASYLUM, Formby, near Liverpool.—Junior Medical Officer. Salary £50 per annum, with board, lodging, and washing. Apply to Dr. S. A. Gill, Formby, Lancashire.

SUFFOLK COUNTY ASYLUM, Ralton, Suffolk.—Second Assistant Medical Officer for three years, unmarried. Salary £100 a year, with board, washing, and attendance.

UNIVERSITY COLLEGE, Bristol.—Faculty of Medicine. Demonstratorship of Physiology. Stipend £125.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE, Cardiff. Assistant Lecturer and Demonstrator in Anatomy. Stipend £120 per annum. Also Temporary Assistant Lecturer and Demonstrator in Physiology for one year. Salary £120. Applications to the Registrar, University College, Cardiff.

UNIVERSITY OF ST. ANDREWS, St. Andrews.—Professors of Materia Medica and Pathology to conduct classes at Dundee.

VICTORIA HOSPITAL FOR SICK CHILDREN, Park-street, Hull.—Lady House Surgeon. Salary £50 per annum, with board and laundry.

Digitized by Google

VICTORIA UNIVERSITY (THE YORKSHIRE COLLEGE), Leeds.—Demonstrator of Pathology. Salary £150.

WESTERN GENERAL DISPENSARY, Stafford-street, Marylebone-road, London.—House Surgeon, unmarried. Salary £80, with board and residence.

WEST HAM UNION.—Resident Assistant Medical Officer for the Workhouse and School. Salary commencing at £100 per annum for the Workhouse and £25 per annum for the Schools, together with the usual residential allowances. Applications to the Clerk, Guardian Offices, Union-road, Leytonstone, E.

WEST RIDING ASYLUM, Wakefield.—Pathologist. Salary £150, increasing to £200.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL, Wolverhampton.—Assistant House Surgeon for six months. Board, lodging, and washing provided, and a small honorarium given.

WORCESTER COUNTY COUNCIL.—Additional County Analyst for the Administrative County of Worcester (exclusive of the County Boroughs of Worcester and Dudley). Salary £400 per annum, payable monthly, together with all necessary out-of-pocket expenses. Applications to the Clerk to the County Council, Shirehall, Worcester.

YORK COUNTY HOSPITAL, York.—Assistant House Surgeon. Salary £60 per annum, with board, rooms, washing, &c.

YORK DISPENSARY.—Resident Medical Officer, unmarried. Salary £150 a year, with furnished apartments, coals, and gas.

Births, Marriages, and Deaths.

BIRTHS.

CROSS.—On July 7th, at Worcester House, Clifton, the wife of F. R. Cross, M.B., F.R.C.S., High Sheriff of Bristol, of a daughter.

FULLER.—On July 3rd, at Fairhaven, Queen's-road, Richmond, the wife of J. Reginald Fuller, M.B., B.S., M.R.C.S., of a daughter.

HOME-DOUGLAS.—On June 29th, at the Braid Hills Hotel, Edinburgh, the wife of A. Home-Douglas, F.R.C.P. Edin., of a daughter.

JAMESON.—On July 4th, at "Laceby," Kent-road, Gravesend, the wife of G. B. Jameson, M.D., of a son.

PREEDY.—On July 11th, at Stanley-gardens, Willesden-green, N.W., the wife of Edward Preedy, L.D.S. Eng., of a daughter.

ROBERTS.—On July 5th, at Kingsthorpe, Church-road, Forest-hill, S.E., the wife of Francis H. Roberts, L.R.C.P. Lond., of a daughter.

ROWE.—On July 6th, at Doctor's Lodge, Borough Asylum, Ipswich, the wife of Edmund L. Rowe, Medical Superintendent, of a son.

SHACKLETON.—On June 14th, at Buff Bay, Jamaica, the wife of T. F. Shackleton, M.R.C.S., L.S.A., of a son.

WEBB.—On July 9th, at Church-street, Stoke Newington, the wife of Albert W. Webb, M.B., M.R.C.S., of a daughter.

MARRIAGES.

BORTHWICK—COWELL.—On July 5th, at St. Pancras Parish Church, William John Walter Winfield Borthwick, M.B., son of the late Colonel Borthwick, of the 8th Madras Native Infantry, to Elizabeth, third daughter of the late Robert Cowell, of Ormesby, Middlesbrough, Yorks.

GILES—TINDALL.—On July 8th, at St. John's Church, Lewisham High-road, Arthur Edward Giles, M.D., B.Sc. Lond., M.R.C.P., F.R.C.S., of Queen Anne-street, W., second son of Samuel Giles of Tyrwhitt-road, S.E., to May Hartree, eldest daughter of Alfred A. Tindall, of Wickham-road, S.E.

HEESON—MILLER.—On July 7th, at Redhill Congregational Church, Edwin Ernest Darley Heeson, L.D.S. Eng., elder son of James Ernest Heeson, of Redhill, to Maude Agnes, eldest daughter of William Miller, of Maybury Lodge, Reigate.

HENDLEY—PETRIE.—On July 7th, at the Parish Church, Eastbourne, by the Rev. J. H. Copleston, Rector of Offwell, Devon, assisted by the Rev. H. B. Ottley, Vicar of the Parish, Surgeon-Captain Arthur Gervase Hendley, I.M.S., youngest son of the late Surgeon-General John Hendley, C.B., to Jessie Graham, eldest daughter of J. H. Petrie, Esq., 5, South Cliff, Eastbourne.

KENDALL—CONSTABLE.—On July 12th, at St. Stephen's Church, Hampstead, Herbert William Kendall, M.R.C.S., L.R.C.P., of King's-parade, Clifton, Bristol, to Elizabeth, third daughter of the late Rev. Henry Constable, M.A., Rector of Desert More, Co. Cork.

LANSDOWN—FULLER.—On July 6th, at the Parish Church, Lydford, Francis Poole Lansdown, M.R.C.S., of Clifton, Bristol, to Sarah Sophia, daughter of the late Wm. Fuller, Moor Lodge, Lydford, Devon.

MUMFORD—JAY.—On July 6th, at St. Mary Abbot's, Kensington, Wilfred George Mumford, M.R.C.S., L.R.C.P., of Bartlett's-passage, Holborn, to Louisa Sylvia Dora, daughter of the late Stephen Octavius Jay, of Addison-crescent, Kensington.

DEATHS.

BOSWORTH.—On July 12th, 1898, at Grove-end, Sutton, Surrey, Emily Sophia, wife of John R. Bosworth, M.R.C.S., &c.

GILL.—On July 11th, at Montreux, Shrewsbury, John Gill, L.R.C.P. Lond., M.R.C.S. Eng., of Welshpool, Montgomeryshire, aged 55 years.

WILSDEN.—On July 9th, at the Vicarage, Wooler, Alfred Wilsden, M.B., second son of Rev. Canon Wilsden, aged 30 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

BRITISH MEDICAL ASSOCIATION MEETING AT EDINBURGH.

DURING the forthcoming meeting of the British Medical Association at Edinburgh the Representatives of THE LANCET can be consulted at the Imperial Hotel with regard to our report of papers and proceedings.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1898, which was completed with the issue of June 25th, and the Title-page to the Volume were given in THE LANCET of July 2nd.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1898 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

THE TERROR OF THE FASHIONABLE HAIR-COMBS.

THE *Manchester Courier* states that two accidents have occurred outside the theatres—the Criterion and the Prince of Wales's are mentioned—owing to the ignition by over-head gas-jets or casual sparks from smokers' pipes, cigars, or cigarettes of "tortoiseshell" combs while worn in the hair. In one case (says our contemporary) the lady would have been seriously injured had not a fireman deluged her with water.

"COMBINATION SURGICAL SCISSORS AND DRESSING FORCEPS."

To the Editors of THE LANCET.

SIRS,—Allow me to say that the above instrument, described by Mr. H. de P. Veale in THE LANCET of June 25th, is no new invention. Some ten years ago while at Guy's Hospital I had made for me by Messrs. Down Brothers an instrument of the kind described which I still possess. It is practically a narrow pair of scissors with the ends flattened and serrated at right angles to the cutting edge of the blades. I was under the impression then that I had invented a new surgical instrument, but I learnt subsequently that the idea was an old one.

I am, Sirs, yours faithfully,

July 1st, 1898. FREDERICK VICARS, M.D. Brux.

"THE PUBLIC PARKS."

To the Editors of THE LANCET.

SIRS,—In your annotation "The Public Parks" in THE LANCET of July 9th you say with regard to the vagrants, "the vermin which infest them are not likely to leave them and roam in the grass." I wish this were the case. Two years ago my little boy of two years old escaped from his nurse and sat down on the grass in Hyde Park for a few seconds or minutes. When he came home more than a dozen active specimens of pediculus were found on his clothes. The little daughter of a physician of my acquaintance had a similar experience. Since that time my children's liberty and pleasure have had to be severely curtailed when in Hyde Park.

I am, Sirs, yours faithfully,

July 9th, 1898. PATERFAMILIAS.

A NEW POCKET MICROSCOPE.

MR. H. WILLIAMS, 90, Shacklewell-lane, Hackney, N.E., has submitted for our inspection a pocket clinical microscope. It consists of a plano-convex lens mounted in a handle. The substance to be examined is spread upon the plane surface moistened with a drop of water. The instrument is of quite sufficient power to show the corpuscles in a drop of blood as separate bodies. Crystals and cells in the urine can also be seen, but we were unable to detect casts by its aid. As it is easily carried about in the pocket it will be found a useful instrument for making a rough diagnosis at the bedside. The price is 10s. 6d., which includes a special case.

"THE TREATMENT OF SEA-SICKNESS."

To the Editors of THE LANCET.

SIRS,—In reply to "M.R.C.S., &c.," whose letter under the above heading appeared in THE LANCET of June 25th, I may say that I have found the following suggestions copied from Dr. Burney Yeo's "Manual of Medical Treatment" very useful: "It is of great importance to follow a careful and simple diet for a week or two before undertaking a sea voyage, and to take two or three doses of aperient medicine during the same period before embarking. Bromide of ammonia is regarded by some ship surgeons as the best of all remedies both for prevention and cure. It should be begun a day or two before embarking on a long voyage; a dose of 20 gr. in an ounce of water with 15 gr. of sodium bicarbonate twice or three times a day. It will remove acidity and promote gastric anæsthesia."

I am, Sirs, yours faithfully,

June 28th, 1898. LATE SURGEON M.D.S.F.

LONGEVITY AND WINE.

ACCORDING to *La Médecine Moderne* red wines are preferable to white wines because the consumers of the former live longest. A viticulturist of the Gironde bethought himself to carry out an investigation as to human longevity in white and red wine districts respectively, taking as his basis the electoral lists in the various departments. Among 7738 electors domiciled in a red wine country he found 381 individuals who were more than seventy-five years old, whereas among 3029 electors belonging to a white wine country there were only 81, an appreciable difference. Yet red wine is more easily adulterated than white wine.

A NEW HYPODERMIC AND ASPIRATION SYRINGE.

IN the current number of the *Deutsche Medicinische Wochenschrift* Dr. F. Lüscher, of Berne, describes a new pattern of syringe which is said to be equally suitable for the giving of hypodermic injections and for the aspiration of considerable quantities of fluid. It consists essentially of an indiarubber air-ball, to the outlet of which is attached one end of a removable glass tube serving as the receiver for the fluid to be either injected or aspirated, the needle or trocar with cannula being in communication with the other end of the receiver. Only one-half of the air-ball is compressible, the other half being rigid, which is found to make it more convenient to work, and by means of a small air-hole, which can be closed at the proper time with the forefinger, the ball can be used either as a force pump or an exhaust pump. Glass receivers for use with the same air-ball may be made in a great variety of sizes and shapes, varying from a capillary tube to a burette having a capacity of 30 c.c. (about 1 fl. oz.). The ends of the receiver can be sealed by fusion for the safe preservation of pathological fluids which have been aspirated. For sterilisation the whole apparatus can be boiled in soda solution for 12 hours without being injured. Further particulars may be obtained from Mr. G. Klöpfer, instrument-maker, of Berne.

A QUESTION OF ETHICS.

THE following has been submitted to us by a medical correspondent who received it from Woodhall Spa. As Northcote House is not the only building at Woodhall Spa where patients can live, and seeing that anyone is perfectly free to choose his own medical man, we think the wording of the circular is unwise.

"NORTHCOTE HOUSE, WOODHALL SPA,

"June 16th, 1898.

"DEAR SIR,—As you may be aware, I have, as a Spa Practitioner with an experience of the virtues of the Woodhall Spa waters extending over many years, circulated amongst our profession a considerable amount of literature, which I have written on the subject from a very early date, when Balneo-therapy, based on scientific principles, was first introduced by me to my medical brethren.

"In consequence patients are frequently sent to Woodhall with letters of introduction to me; but it has recently come to my knowledge, from letters written to me by my professional friends, that patients sent by them have, on their arrival, been led to go into lodgings, or to hotels, where representations have been made to them, whereby they have been induced to consult other Practitioners.

"Feeling sure that you would disapprove of such a reprehensible practice as that of which I complain, I should be much obliged, in case you should be desirous to place any of your patients under my care, if you would be good enough to warn them against such representations, or to forward to me a copy of your letter of introduction in order that I may call on them on their arrival.

"Yours faithfully,

"ROBERT CUFFE,

"Vice-President of the British Balneological and Climatological Society."

UNFORTUNATE PUBLICITY.

A CORRESPONDENT has sent us Messrs. Cox and Sharland's South of England Monthly Time Tables, in which we find the following unfortunate advertisement:—

REGISTER OF
TESTS FOR DEFECTIVE VISION
OF
CHILDREN IN SCHOOLS,
WITH INSTRUCTIONS FOR USE,
BY
J. F. BULLAR, M.A., M.B. CANTAB., F.R.C.S. ENG.
(Ophthalmic Surgeon to the Southampton Eye & Ear Hospital),
AND
T. G. ROOPER, M.A. OXON.
(H.M. Inspector of Schools).
LONDON:
GEORGE PHILIP & SON 32 FLEET STREET.
SOUTHAMPTON:
COX & SHARLAND, 150, HIGH STREET.
ENTERED AT STATIONERS HALL.

Dr. Bullar should instruct his publishers to withdraw this advertisement from a publication which must have a wide lay circulation.

THE CURSE OF CIRCULARS.

PROBABLY no class of men is more pestered with irritating and useless circulars, sent through the post and often disguised in the form of letters, than are medical men. A correspondence on the subject, from the point of view of the general public and of the senders of the circulars, has been published in a daily contemporary, originated by a writer who suggested methods—vigorous, certainly, and possibly in a measure effective, but at the same time likely to lead to worse inconveniences than the evil itself. This gentleman gives his servants orders to destroy all circulars coming to his house, but complains that even then some of them elude the vigilance of his "well-trained butler" and are forwarded to him with his letters when he is away from home. Now it is clear on reading the list which he gives and from the rest of his letter that even those advertisements which come in duly stamped and sealed envelopes he leaves to be opened and dealt with summarily by his domestics. A well-trained butler is not possessed by everybody and the page boy and the parlourmaid are apt in such circumstances to tear up and burn important notices

Digitized by Google

such as lawyers at times necessarily send to their clients—notices of meetings of companies and societies which the intended recipient would regard as important, dividend warrants, calls upon shares and other documents which come in long envelopes and are wholly or partly printed, while they would be sure to forward with scrupulous care or to lay on the study table the lithographed letter of the bishop who proposes to lecture on the Holy Land at Jerusalem, or to rebuild his cathedral, and the coroneted card which invites to a public dinner at which a nobleman will preside, and at which a collection will be made, together with the often carefully-veiled missive of the money-lender and the masseuse. The cheapening of the post has added an impetus to the flood of circulars and as far as we can see no combined action of the public is ever likely to check it. It may gradually be discovered that such advertisements do not pay, but meanwhile the busy man will have to glance through the contents of his letter-box himself or he will some day miss seeing something important and perhaps have serious cause to regret that he did so.

PIOUS CONFIDENCE.

THE *Christian World* of July 7th prints an amusing example of the pious confidence which the Pasha of Damascus—like probably the majority of his congeners—is prepared to put in Allah as a practical statistician and sanitarian. The French statistical department, anxious to obtain definite information on certain matters from the Turkish provinces, sent lists of questions, to which they requested replies, to the various provincial pashas. Certain of the questions were addressed to the Pasha of Damascus and his replies ran, according to our contemporary, as follows:—

Question: What is the death-rate per thousand in your principal city? Answer: In Damascus it is the will of Allah that all must die; some died old, some young.

Question: What is the annual number of births? Answer: We don't know; only God alone can say.

Question: Are the supplies of drinking water sufficient and of good quality? Answer: From the remotest period no one in Damascus has ever died of thirst.

Question: General remarks on the hygienic condition of your city? Answer: Since Allah sent us Mohammed his prophet to purge the world with fire and sword there has been a vast improvement. But there still remains much to do. Everywhere is opportunity to help and to reform. And now, my lamb of the West, cease your questioning, which can do no good either to you or to anyone else. Man should not bother himself about matters which concern only God. Salem Aleikum!

It is clear that the doctrine held by the Christian that God helps those who help themselves finds no favour in the municipal government of Damascus.

SEBORRHŒIC ECZEMA AND OTHER ILLS.

To the Editors of THE LANCET.

SIRS,—May I, through the medium of THE LANCET, ask a brother professional to give me a hint? I have for some years suffered from seborrhœic eczema, indigestion, constipation, and hæmorrhoids. For three years I have had sighing respirat'on (what does that point to?). The patches of skin affection are on the scalp, trunk, and limbs, and are at times troublesome. What can I do or apply to get relief, if not a cure? Arsenic increases the indigestion, ichthyol irritates. My habits are simple; my only indulgences are a little stimulant and a little tobacco in the evening. I am, Sirs, yours faithfully,

July 4th, 1898. A. B. C.

Lux.—There should be a fair price for such a nucleus and our correspondent has a right to take measures to obtain it. Of course, full information should be given to, and is certain to be demanded by, the intending purchaser. From a year to a year and a half's purchase would probably meet the case, but the figure must be settled by inspection of the books.

Mr. A. Foster Clarke.—We do not find the person's name on the Medical Register, so that he would seem not to come under the disciplinary jurisdiction of the General Medical Council—at any rate, while their sphere of action has its present limitations.

Ribald.—A good signature and, in a way, a proper communication. But why does our correspondent adopt a phraseology which prevents us from publishing the letter?

F.R.C.S. (Southsea).—We have asked the author for the name of his publisher. The Jacksonian Prize Essays are not published in the medical press.

Democraticus is referred to a small publication issued from THE LANCET office entitled "Difficulties under the Infectious Diseases (Notification) Act."

Subscriber (Ashby-de-la-Zouch). — The Colonial Office. For the healthier and more popular places there are always many candidates.

Rusticus.—The inquest was held before the coroner for West London in July, 1895, and was fully reported in most of the daily papers.

Senior should communicate with Dr. Fletcher Little, 32, Harley-street, Cavendish-square, who will give all information.

Tussis.—We do not prescribe. The medical attendant will recommend a further opinion if he considers one necessary.

J. L.—The library as a medical library is by no means good or up to date. It contains some valuable old books.

Alpha.—The Students' Number will be published on Sept. 3rd, 1898.

Legalis.—The parallel has been frequently drawn.

F.R.C.S. Edin.—It is certainly preferable.

Mrs. S. G.—2, Fitzroy-square.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (18th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Terms for Position Pages and Serial Insertions on application.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

AN ABSTRACT OF AN

Address

ON

INTESTINAL CANCER AND ITS TREATMENT.

Delivered before the Leamington Medical Society on March 22nd, 1897,

BY THE LATE J. GREIG SMITH, M.A. ABERD., F.R.S. EDIN.,

PROFESSOR OF SURGERY, UNIVERSITY COLLEGE, BRISTOL; SURGEON TO THE BRISTOL ROYAL INFIRMARY.

[AFTER some preliminary remarks the lecturer proceeded to demonstrate from specimens some points in the pathology of intestinal cancer which were of importance practically. These specimens, which were chiefly from cases operated upon by himself and which were mounted in transparent media between plates of glass and stained or otherwise treated, showed clearly by reflected and by transmitted light details in the tumour-structure and in the invasion of individual parts which are not visible under ordinary methods of mounting. The points to which the lecturer specially called attention were two: 1. The heaping up of fatty tissue all around ordinary cancer of the intestine. In the later stages of the disease when all the intestinal walls were destroyed the continuity of the canal depended often entirely on the presence of this fatty tissue. 2. The position of the glandular or acinous growth outside the fibrous or cicatrising elements; its instability; and, generally, its behaviour in the scheme of growth.]
